ACKNOWLEDGEMENTS

During this fulfilling and rewarding journey of my doctoral studies, I have been fortunate to receive invaluable support and guidance from many individuals. I would like to express my sincere appreciation to all those who have contributed to my academic and personal growth.

I am deeply grateful to my supervisor, Dr. K.W. Thilini Chethana, for her invaluable guidance and unwavering support throughout my PhD studies. She has provided me with essential academic direction and has always been patient and dedicated in mentoring my research. Her professionalism, strong sense of responsibility and pursuit of excellence have profoundly influenced my work. I truly appreciate her mentorship in shaping both my scientific thinking and academic development.

I am truly indebted to my co-advisor, Prof. Dr. Kevin D. Hyde, a distinguished mycologist whose remarkable contributions to fungal research have been a constant source of inspiration. His profound expertise and constructive suggestions have greatly deepened my understanding of mycology. I am especially grateful for the opportunity he provided me to study at the Centre of Excellence in Fungal Research (CEFR), Mae Fah Luang University, where I have benefited immensely from his guidance and the dynamic academic environment.

I sincerely appreciate my external advisor, Prof. Dr. Jiye Yan, for his crucial role in shaping my research direction and supporting my academic growth during my time at the Beijing Academy of Agriculture and Forestry Sciences. Beyond offering financial support for my PhD studies, he has consistently provided invaluable insights and encouragement, which have significantly influenced both my scholarly pursuits and overall development. I am immensely grateful for the valuable platforms and opportunities he has provided me throughout my research.

My heartfelt appreciation extends to Prof. Dr. Wei Zhang and Prof. Xinghong Li for their generous support and valuable insights into my topic design, field collection and research planning. Their expertise in plant pathology and invaluable advice have greatly enriched my knowledge and strengthened my scientific foundation. I am profoundly grateful to Dr. Ruvishika S. Jayawardena, Dr. Ishara S. Manawasinghe and

Dr. Pranami D. Abeywickrama for their selfless guidance and unwavering encouragement throughout my studies and research. They patiently addressed my inquiries, generously shared their expertise, and inspired me to overcome challenges. Their kindness and wisdom have been instrumental in my growth. I owe special thanks to Prof. Alan J. L. Phillips for his exceptional guidance. His expert instruction in laboratory techniques and scientific writing has profoundly influenced my academic development. His rigorous scholarship and unwavering commitment to scientific excellence continue to inspire my scholarly pursuits.

In addition, I would like to express my gratitude to Dr. Rajesh Jeewon, Dr. Kaichun Zhang, Ms. Jing Wang, Ms. Guangqin Wen, Dr. Janith Aluthmuhandiram, Dr. Khanobporn Tangtrakulwanich, Mr. Kasiphat Limsakul, Ms. Wilawan Punyaboon for their help and guidance. I am grateful to Dr. Ying Zhou, Dr. Mei Liu, Dr. Qikai Xing, Dr. Yonghua Li, Dr. Chenfang Wang, Dr. Hui Wang, Dr. Caiping Huang, Dr. Junbo Peng and Dr. Xuncheng Wang for their advice and support. My gratitude goes to Ms. Linna Wu, Mr. Pengzhao Chen and Ms. Anran Fan for their generous assistance in my research.

I would like to thank Beijing Academy of Agriculture and Forestry Sciences (KJCX20210403), Beijing Municipal Science and Technology Project (Z201100008020014), China Agriculture Research System of MOF and MARA (CARS-29) and Outstanding Scientist Grant of the Beijing Academy of Agriculture and Forestry Sciences (JKZX202204) for their financial support. Beijing Key Laboratory of Environment Friendly Management on Fruit Diseases and Pests in North China, Institute of Plant Protection, Beijing Academy of Agriculture and Forestry Sciences is thanked for supporting morphological and molecular work in China.

Furthermore, I wish to thank the researchers and staff in the Centre of Excellence in Fungal Research, Mae Fah Luang University, and Institute of Plant Protection, Beijing Academy of Agriculture and Forestry Sciences for their immense help in my research and life. I would also like to thank my fellows in BIPP: Aining Guo, Baoyu Wang, Bowen Hao, Gan Wang, Hui Guo, Jiao Zhang, Jiawen Wu, Jinpeng Wang, Kaixuan Ren, Meng Wang, Nannan Wang, Qi Wang, Shuo Jin, Wenwen Liang, Xiaona Duan, Xinfang Wang, Yimeng Zhang, Yunyun Chen, Zeshun Chen, and fellows in CEFR: Achala Jeevani, Anujani Gunarathne, Ayesha Madushani, Bei Pang, Chao Chen,

Carlo Chris Serrano Apurillo, Chunfang Liao, Cuijinyi Li, Dan Xiong, Dilini Thakshila, Haijun Zhao, Hongde Yang, Hongli Su, Hongwei Shen, Hua Li, Jian Ma, Jianwei Liu, Jingyi Zhang, Le Luo, Lei Lei, Li Lu, Lijuan Zhang, Lin Li, Lingling Yuan, Lixue Mi, Na Wu, Peixuan Yu, Omid Karimi, Ping Liu, Qian Zeng, Qingfeng Meng, Raheleh Asghari, Rongju Xu, Ruifang Xu, Samhita Mukhopadhyay, Shucheng He, Shuxin Bao, Tharindu Bhagya, Tianjun Yuan, Tianye Du, Tinghong Tan, Tony Attapon, Veenavee Silva, Xia Tang, Xian Zhang, Xiangfu Liu, Xingcan Peng, Xingjuan Xiao, Xinyu Zhu, Xixi Han, Yanyan Yang, Yaru Sun, Ying Gao, Ying Li, Yinru Xiong, Yongxin Shu, Yu Yang, Yuanhao Ma, Yunhui Yang, and others friends for their kind help, invaluable advice and sincere friendship.

Last but not least, I would like to express my deepest gratitude to my parents and family for their unconditional support and unwavering encouragement throughout my PhD journey. No words can fully convey my appreciation for their selfless dedication and boundless love. I am also immensely grateful to my friends for their heartfelt encouragement and thoughtful care. I truly cherish the invaluable friendship we share. Special thanks to Yameng Li and Yiwei Han; their steadfast trust and constant companionship have been my greatest source of strength and motivation.

ABSTRACT

Cherry, grapevine, and blueberry are important fruit crops in China, valued for their high economic and nutritional significance. However, they are susceptible to various fungal diseases caused by multiple pathogens, which severely impact fruit production and quality, leading to significant economic losses. Although extensive research has been conducted on fungal pathogens causing these diseases, most studies have only focused on a single fungal taxon or one type of disease. Additionally, inconsistencies in identification methods and the lack of adherence to the latest fungal classification systems have led to confusing and potentially misleading results. The objectives of this study are to: (1) investigate the occurrence of important diseases affecting cherry, grapevine and blueberry across different cultivation regions in China and identify the associated fungi. This will help explore emerging and potential fungal pathogens, dominant disease-associated fungal communities, as well as the relationship between fungi, disease types and their distribution; (2) Compile fungal pathogen data by integrating results from this study with previous research, providing an updated and systematic summary that aligns with the latest fungal classification. Given their widespread occurrence and significant impact, cherry leaf spot (CLS) and grapevine trunk diseases (GTD) were selected to study their associated fungal communities; For blueberry, as emerging diseases and pathogens have been frequently reported in recent years, a comprehensive identification was conducted on fungi associated with important diseases, including fruit rot, leaf spot, stem blight and root rot. Fungal species were identified based on morphological characters and multi-locus phylogenetic analysis, and pathogenicity tests were performed on selected fungal isolates.

As a result, three *Colletotrichum* species from Beijing, seven *Fusarium* species from three provinces (including six new host records), six *Cladosporium* species from Beijing (including five new host records), as well as one *Neopestalotiopsis* and one *Diaporthe* species were identified from different symptom types of cherry leaf spot. The pathogenicity of *Colletotrichum* and *Fusarium* species was verified, and all fungal species reported as CLS pathogens were summarized. For grapevine trunk disease, forty species associated with Botryosphaeria dieback, black foot disease, and Diaporthe dieback were identified across eight provinces. These species belonged to twenty-one genera, including twelve new host records. The dominant genera included *Diaporthe*, Botryosphaeriaceae, *Cylindrocarpon*-like and *Fusarium*-like species, providing a comprehensive summary and supplementation to existing GTD studies. On blueberry, fruit rot, leaf spot, stem blight and root rot diseases were comprehensively investigated from five provinces, seven pathogens causing blueberry fruit rot were identified, and 103 species from forty fungal genera were recovered from the other three diseases. *Alternaria*, *Botryosphaeria*, *Fusarium*, *Neopestalotiopsis*, and *Pestalotiopsis* are the five most prevalent genera associated with leaf spot, stem blight and root rot, accounting for nearly 50% isolation ratio. The prevalence of the fungal genera in isolation sources and regions was preliminarily analysed. Species from the dominant genera *Neopestalotiopsis* and *Pestalotiopsis* were characterized and described, including seventeen new host records and three new species. Additionally, pathogenicity assays were conducted on seven species causing fruit rot and three species causing stem blight. Finally, a comprehensive summary of fungal pathogens associated with blueberry diseases in China was compiled. The current study is a continuation, expansion and conclusion of fungal species associated with cherry leaf spot diseases, grapevine trunk diseases and blueberry diseases in China, relevant results provide an insight into the overall occurrence of the diseases, as well as an important basis on the diagnosis and management of the diseases.

Keywords: China, Cherry Leaf Spot, Grapevine Trunk Disease, Blueberry, Pathogens, Phylogenetic Analysis, Morphological Characterization, Pathogenicity Test, Taxonomy

CHAPTER 1

INTRODUCTION

1.1 Current Status of Cherry, Grapevine and Blueberry Cultivation in China

The cultivation of fruit crops has a long history, which can be traced back to 6000 to 3000 BCE (Janick, 2005). However, the studies on the domestication of fruit trees are much less than those on herbaceous annuals serving as food sources (Goldschmidt, 2013). Compared with annual crop plants, cultivating fruits requires more complicated technologies and long-term management (Janick, 2005). In the past decade, improvements in fruit cultivation technology have greatly accelerated the expansion of the yield of fruit crops (Rajan et al., 2021). Fruit is a good source of multiple nutrient elements, including vitamins, fibres, carbohydrates, and minerals, and can promote physical fitness in humans by reducing the risk of diseases and delaying senescence (Vicente et al., 2009).

Cherry (*Prunus*, Rosaceae) is native to Europe and Asia regions with more than 2,000 years of cultivation history and is currently an economically important fruit widely cultivated in temperate and subtropical regions of the Northern Hemisphere (Blando & Oomah, 2019; Song et al., 2024). In the past two decades, global cherry production has grown by 37% (Vignati et al., 2022). Among more than 50 species of cherry, *Prunus avium* (sweet cherry), *P. cerasus* (sour cherry), *P. pseudocerasus* (Chinese cherry) and *P. tomentosa* (Nanking cherry) are the most commonly consumed edible species, which are used for fresh eating and processed into products, such as jam, juice and dried fruits (Cao et al., 2015; Song et al., 2024). Sweet cherry (*Prunus avium* L.) is one of the most widely consumed and popular cherry species, known for its bright appearance, delicious taste, and high nutritional value. Sweet cherry is rich in essential nutrients and bioactive components, including vitamin C, fibre, minerals and polyphenols, which contribute to its anti-oxidant and anti-inflammatory properties. Additionally, sweet cherry consumption has been linked to a reduced risk of

cardiovascular diseases, diabetes, and cancer (Kelley et al., 2018). In recent years, sweet cherry production in China has grown rapidly, making the country the world's largest producer (Zhang et al., 2024a). As of 2021, the total area of sweet cherry plantations in China reached 233,334 ha, with an annual yield of 1,600,000 tons. The main production regions include Shandong, Liaoning, Shaanxi, Henan, Shanxi, Sichuan, Gansu, Hebei, and Beijing (Zhang et al., 2024b). Currently, 30 to 50 main cultivars are grown in China, such as 'Hongdeng', 'Tieton', 'Summit', 'Brooks', 'Lapins' and 'Sunburst'; and over 50 to 60 new cultivars are being tested or promoted (Zhang, 2017; Zhang et al., 2024b).

Grapevine (*Vitis* spp.) is a perennial climbing plant in the Vitaceae. Among more than 100 described species, *Vitis vinifera* L., known as the common grapevine, is the most widely planted species for its edible fruit. Other species, such as *V. rupestris*, *V. riparia* and *V. berlandieri*, are primarily used as breeding rootstock due to their resistance to pathogens (Terral et al., 2010; Gramaje et al., 2018). Grapevine is one of the longest-domesticated fruit crops, dating back to 6000 BCE in regions, including Iran, the Caucasus and Anatolia, before spreading throughout the Near East and Europe. Vine growing and winemaking have long been symbolic of human societies and civilizations (Limier et al., 2018). Nowadays, grapevines are widely cultivated in temperate and subtropical regions around the world (Terral et al., 2010). There are 6,000–10,000 different grapevine cultivars, but only 400 hold economic and commercial significance (Limier et al., 2018; Vignani & Scali, 2024). In 2022, the global vineyard area reached 7.3 million ha, with grape production totalling 80.1 million tons. Of this, 50% was used for wine production, 42% for table grapes, and 7% for dried grapes. Spain, France, China, Italy and Turkey are the top five grape-cultivation countries (OIV, 2023). Grapevine cultivation and the wine industry in China have developed rapidly over the past 30 years. Grapevines are currently cultivated in more than 20 provinces and municipalities in China, with the main production concentrated in Xinjiang, Shandong, Liaoning, and Hebei Provinces (Li et al., 2015). Among grape-cultivation countries, China ranks third in cultivation area of 785 Kha and ranks first in annual grape production, reaching 15 million tons (OIV, 2023).

Blueberry (*Vaccinium* spp.), a perennial shrub of the family Ericaceae, has been cultivated for more than 100 years. Commercial varieties of blueberry mainly include

highbush (*Vaccinium corymbosum*), lowbush (*Vaccinium angustifolium*) and Rabbiteye (*Vaccinium virgatum*) (Edger et al., 2022). Blueberries are recognized as a “superfruit” for their rich nutrients, including vitamins (C and K), minerals (calcium, iron, magnesium, manganese and zinc), dietary fibre (2.4–3.5% of fruit weight) and polyphenols (anthocyanins and flavonols) (Krishna et al., 2023). Specifically, anthocyanin flavonoids, which account for up to 60% of the total polyphenolics in ripe blueberries, may make the greatest contribution to the health benefits of blueberry in reducing risk of cardiovascular disease, death, and type 2 diabetes, as well as improving weight maintenance and neuroprotection (Kalt et al., 2020). The blueberry industry has developed rapidly in recent years, with global production more than doubling in the past decade (U.S. Department of Agriculture, 2021). According to the data issued by the International Blueberry Organization (2024), the global area for blueberry cultivation reached 262,417 hectares in 2023, with a total production of 1.78 million tons. China has been the top producer of blueberries in the world, with 77,641 hectares of growing area and 0.56 million tons of production, followed by the United States, Peru, Chile, and Canada. Blueberry was first introduced into China in the 1980s and is now planted in 26 out of 34 provinces, mainly distributed in the Northeast, Shandong province, Southeast, and Southwest of China (Yu et al., 2012; USDA, 2023).

Due to their contribution to the economy, cherries, grapevines, and blueberries are important fruit crops in China. The quality and nutrient composition of fruits are highly dependent on environmental conditions and agricultural practices, including fertilization, irrigation, and weed and pest control. Good management techniques are crucial to the sustainable development of the fruit industry (do Nascimento Nunes, 2008; Askari-Khorasgani et al., 2019; Yuan et al., 2022).

1.2 Plant Diseases and Fungal Identification

1.2.1 An Overview of Plant Diseases and Fungal Pathogens

Plants can be affected by diseases throughout their life cycle and on all parts of their organs. Of the 36.5% global total losses caused by diseases, insects, and weeds in crop production, 14.1% are caused by diseases. Plant diseases are divided into non-

infectious diseases caused by abiotic factors (such as drought, salinity, heat, cold and nutrient stress) and infectious diseases caused by biotic factors (such as fungi, bacteria, viruses and nematodes) (Atkinson & Urwin, 2012; Oliver, 2024).

As an important group of plant pathogens, fungi have a huge impact on agricultural production. There were numerous examples of severe damage caused by fungi and fungus-like organisms throughout history. The Irish Potato Famine in the 1840s, widely regarded as one of the most devastating historical events, resulted in the deaths of approximately one million individuals and forced an equal number to flee their homeland. The trigger of the disaster is potato late blight caused by *Phytophthora infestans* (Oomycetes) (Turner, 2005). Coffee rust caused by *Hemileia vastatrix* is the most destructive disease of coffee; its outbreak in 1869 in Ceylon (now Sri Lanka) destroyed Ceylon's coffee industry, forcing planters to grow tea instead (McCook & Vandermeer, 2015). Fusarium wilt on bananas, also known as Panama disease, is caused by *Fusarium oxysporum* f. sp. *cubense*. The disease destroyed 40,000 ha of the cultivar Gros Michel in Central America from the 1890s to the 1950s (Pérez-Vicente et al., 2004). Currently, around 8,000 species of fungi have been reported to cause plant diseases, affecting trees, shrubs, grasses, cereals, vegetables, and fruit crops. These pathogens can lead to 30–40% of crop losses, amounting to hundreds of billions of dollars annually (Xu, 2022). Given that fungal pathogens continue to pose a significant threat to plant biodiversity, crop production and food security, it is essential to adopt strategies, such as disease surveillance, disease-resistant breeding, improved agricultural practice, and international research collaboration (Fisher et al., 2020).

1.2.2 Common Diseases of Fruit Trees and Related Pathogens

Fungal diseases could occur on any part of the fruit trees, including the leaves, trunks (stems), roots, flowers and fruits. Some are grouped according to the plant organ they affect and symptoms they cause, such as leaf spots, blights, wilts and root rots; and some have specific names like grey mould caused by *Botrytis cinerea*, and anthracnose caused by *Colletotrichum* spp. (Dean et al., 2012; Oliver, 2024). Diseases of fruits directly influence the quality and the yield of fruits. For example, Botrytis fruit rot or grey mould is one of the most common and destructive diseases on many fruit crops such as strawberry, pear, kiwifruit, grape and blueberry, causing decay of fruits at both preharvest and postharvest stages, leading to 20–50% loss in severe case (Dwivedi et

al., 2024). Brown rot caused by *Monilinia* spp. also affects a wide range of fruits, especially *Prunus*, including almond, cherry, peach and plum, resulting in 1.7 thousand million Euro in economic loss annually (Lino et al., 2016). Moreover, post-harvest diseases of fruits also represent a significant challenge, contributing up to 50% of global fruit losses annually. *Botrytis cinerea*, *Alternaria alternata*, *Colletotrichum* spp. and *Penicillium* spp. are common fungal pathogens (Pétriaccq et al., 2018).

Though diseases on fruits were studied more extensively, diseases on other organs cannot be overlooked and even have more profound implications. Foliar diseases, such as leaf spots, leaf blights, leaf rust, downy mildew and powdery mildew, are caused by various fungal species depending on the host (Jain et al., 2019). The leaf damages cause a reduction in photosynthesis and carbohydrate production, resulting in indirect yield loss (Roloff et al., 2007; Jermini et al., 2010; Gruber et al., 2012). Trunk diseases cause symptoms, such as blights, cankers, dieback, gummosis and wood rotting, leading to tree death in severe cases (Guarnaccia et al., 2023). Their causal agents mainly belong to Botryosphaeriaceae, Calosphaeriaceae, Cytosporaceae, Diaporthaceae, Diatrypeaceae, Nectriaceae and Togniniaceae (Martino et al., 2024). Root diseases caused by various fungi (especially *Fusarium* and *Rhizoctonia*) and Oomycetes (especially *Pythium* and *Phytophthora*) threaten various fruits. For being underground, they are often difficult to detect in the early stages, but when aboveground parts appear to have symptoms, it may be too late to recover (Williamson-Benavides & Dhingra, 2021). In practical field conditions, symptoms induced by a pathogen are usually not confined to a specific organ, such as anthracnose caused by *Colletotrichum* presents symptoms on both leaves and fruits, and *Fusarium* can cause fruit rot, leaf spots and crown rot (Fu et al., 2019; Zakaria 2023).

Whether pome fruits (such as apples and pears), stone fruits (such as peaches, plums, and cherries), berry fruits (such as blueberries and cranberries), grapevine, citrus or mangoes, all fruit crops are susceptible to various fungal diseases. The severity of these diseases depends on factors such as host susceptibility and environmental conditions (Pétriaccq et al., 2018; Jain et al., 2019; Williamson-Benavides & Dhingra, 2021; Martino et al., 2024). Effective management practices are essential to protect crops from infections, and disease resistance remains one of the main considerations in breeding programs (El-Baky & Amara, 2021).

1.2.3 Complexities of Plant-Associated Fungal Pathogens

1.2.3.1 Undetermined number. The global number of fungal species is estimated to be 2.5 million, though the exact number of plant fungal pathogens remains undetermined (Hyde et al., 2024). Some pathogens can be directly observed on the surface of plants with the naked eye or under a microscope, while most are located inside the plants and need to be examined at the margins of the affected tissues or the vascular tissues (Oliver, 2024).

1.2.3.2 Mixed infections. In the field, the occurrence of some diseases is often caused by the co-infection of multiple pathogens rather than a single pathogen, which can influence the course and severity of the disease (Abdullah et al., 2017). These factors contribute to the challenges of disease diagnosis under practical field conditions. Misdiagnosis and inaccurate identification of pathogens can result in inappropriate control measures, leading to economic loss, environmental disruption and development of resistant pathogen strains (Crous et al., 2015; Srinidhi et al., 2021). Therefore, it is crucial to properly identify the disease and the causal agents.

1.2.3.3 Life mode transfer and latent infection. Among the diverse fungi associated with plants, phytopathogens represent a relatively small proportion, while others function as endophytes or saprobes. Most endophytic fungi colonizing plants can protect their hosts by promoting plant growth and activating systemic resistance. Saprobes are typically decomposers that live on dead organic matter without causing any disease (Carris et al., 2012; Akram et al., 2023). However, some endophytes could switch to pathogens under certain conditions, such as environmental stress and host senescence or host shift (Hrycan et al., 2020; Bhunjun et al., 2024). For example, some strains of *Fusarium oxysporum* cause wilt disease on plant hosts, while others grow asymptotically as endophytes or even enhance host resistance to other fungal pathogens (Redkar et al., 2022). Several fungi associated with grapevine trunk diseases, such as *Botryosphaeria dieback*, were also detected in asymptomatic grapevines, suggesting that some of these fungi may act as latent pathogens in grapevines, with their activity influenced by abiotic or biotic triggers and initial inoculum concentrations (Hrycan et al., 2020). Based on various evidence, Bhunjun et al. (2024) proposed that an endophytic lifestyle is a common strategy in most fungi, and some pathogens also have endophytic ancestors. Lifestyle switches also occur between pathogens and

saprobies. Most pathogenic fungi can survive on dead plant material as saprobies to overwinter, becoming the primary inoculum when environmental conditions are suitable for infection; some opportunistic species, also known as facultative pathogens, survive as saprobies on dead organic matter, but can also infect living organisms (Sharon & Shlezinger, 2013; Jayawardena et al., 2018). Hofstetter et al. (2012) also hypothesised that the fungal pathogens associated with esca disease, a significant threat to grapevine, are likely saprobies that accelerate the decay of senescent or dead wood caused by intensive pruning, frost or other mechanical injuries like grafting.

To sum up, the identification, infection mechanism and interactions between disease-associated fungi are complicated. Comprehensive identification of disease-associated fungi (all fungi generated from diseased plant tissues) is a necessary basis for further research on the diagnosis, epidemiology, disease mechanism, and biocontrol strategies of the plant disease.

1.2.4 Research Advances on Fungal Identification

Scientific names are crucial in studying fungi, including their ecology, applications, threats, and conservation (Cheek et al., 2020). In plant pathology, identifying and naming fungi is fundamental for determining the causal agents of disease and understanding their biology, distribution, host range, potential risk and control strategies (Crous et al., 2015; Manawasinghe et al., 2021). However, fungi remain largely unexplored due to the challenges in research, including their cryptic lifestyles, deficiency in discriminative morphological characters, and the frequent occurrence of convergent evolution. Current estimates suggest that over 50% of plant species have likely been identified, while more than 90% of fungi remain undiscovered (Cheek et al., 2020).

Traditionally, the identification of pathogenic fungi was based on morphology and host associations. However, overlapping morphological characteristics, separate names for sexual and asexual morphs, and ambiguous relationships between fungi and hosts led to species delimitation often indistinguishable and confusing (Jayawardena et al., 2021). With the development and application of DNA sequencing technology, molecular phylogenetics is gradually popularized to assess species boundaries, which resolve the cryptic species, and link asexual and sexual morphs of the same fungus, and phylogenomics derived from genomic data further advanced species delimitations and

higher-level classifications (Chethana et al., 2021; Hyde et al., 2024). In spite of this, phylogeny sometimes also has limitations that lead to misleading and inaccurate inferences. A polyphasic approach combining biology, ecology, morphology and phylogeny is necessary for species definition (Chethana et al., 2021).

1.2.5 The Relationship Between Fungal Taxonomy and Pathogenic Fungal Identification

Most phytopathogenic fungi are ascomycetes, and many of them are pleomorphic, which means that the fungi have both sexual and asexual states. In the mid-nineteenth century, people became aware of the phenomenon that different morphs of the same fungal species existed. To resolve the complex situation, a dual nomenclature system was established. Independent names were assigned to different morphs, such as *Diaporthe* (sexual) and *Phomopsis* (asexual), *Gibberella* (sexual) and *Fusarium* (asexual), and *Glomerella* (sexual) and *Colletotrichum* (asexual) (Wingfield et al., 2012; Jayawardena et al., 2021). Over the past two decades, the rapid advancement of molecular techniques has provided unprecedented insights into fungal taxonomy and systematics. However, the chaos and confusion caused by dual nomenclature led to increasing debate, eventually prompting taxonomists to consider abandoning the dual system. Since January 1st, 2013, the “one fungus-one name” rule was implemented, meaning only one name would be adopted for each fungal species (Wingfield et al., 2012; Manawasinghe et al., 2021). Most names are selected based on priority, such as *Fusarium* over *Gibberella*, and *Diaporthe* over *Phomopsis* (Rossman et al., 2013; Rossman et al., 2015). However, some younger but more commonly used names are exceptions, such as *Colletotrichum* over *Glomerella* (Jayawardena et al., 2021).

Due to the different areas of focus and expertise, plant pathologists sometimes find the ongoing changes in fungal taxonomy confusing. They face challenges in identifying and naming pathogenic fungi according to the latest classifications, while also trying to link scientific names to prior knowledge that is more familiar and acceptable to farmers or researchers working at the frontline dealing with plant pathogens (Crous et al., 2015; Manawasinghe et al., 2021). Two typical examples are as follows:

1. New pathogen name with old disease name. According to the “One fungus, one name” principle, *Diaporthe* takes precedence over *Phomopsis* by publication date (Rossman et al., 2015). However, many *Diaporthe* species were previously widely known as *Phomopsis* in books and literature (Udayanga et al., 2011; Oliver, 2024). Both *Diaporthe* (1309 epithets) and *Phomopsis* (983 epithets) have a huge number of epithets listed in Index Fungorum (<https://indexfungorum.org/Names/Names.asp>, Accessed in March 2025). Currently, diseases caused by *Diaporthe*, such as leaf spot, blight, and canker, are still commonly known as *Phomopsis* blight/ stem canker/ cane and leaf spot (Fedele et al., 2024; Goutam et al., 2024; Underwood & Misar, 2024). In addition, some *Phomopsis* species, such as *Phomopsis asparagi* and *Phomopsis longanae*, have not transferred to *Diaporthe*, which are still legitimate (Sun et al., 2024; Zheng et al., 2025).

2. Wider use of old fungal names in some pathogens. Apple Valsa canker is a devastating disease of apple around the world, which was first reported more than 100 years ago. *Valsa mali* is the dominant pathogen responsible for causing severe tree branch deaths and significant yield losses (Feng et al., 2023). Though *Valsa* is now classified under *Cytospora* based on the priority of the latter (Rossman et al., 2015), due to its long history and substantial impact, most research on the mechanisms and control of the pathogen still uses the name *Valsa mali* (Meng et al., 2024; Li et al., 2025). Additionally, some plant pathologists have discussed the conflict between the well-known name of the pathogen and its identity transformation under the “One Fungus = One Name” system (Wang et al., 2020).

Despite these challenges, given the trends toward comprehensive development of fungal research, the “One Fungus = One Name” rule serves as a simple, accurate, and efficient standard for fungal nomenclature (Hyde et al., 2024). In plant pathology, using the correct name is essential for disease diagnosis, quarantine and management, which further contributes to guaranteeing biosecurity, supporting international trade, and advancing scientific research (Jayawardena et al., 2021).

In conclusion, plant diseases represent an inevitable challenge throughout the life cycle of crops. As economically important fruit crops in China, cherry, grapevine and blueberry are subjected to various fungal pathogens, exhibiting both diversity and complexity. The identification methods and classification standards of fungal pathogens have undergone numerous changes and continue to evolve. It is crucial to understand both the disease characteristics and the organism’s taxonomy. Polyphasic approaches, particularly

involving morphological characters and phylogenetic analysis, are necessary for accurate identification. Additionally, biological and ecological factors, such as host and geographical distribution, should also be considered in the identification process.

1.3 Fungal Diseases of Cherry, Grapevine and Blueberry

1.3.1 Fungal Diseases and Pathogens of Cherry

In the previous research, common fungal diseases on cherry include anthracnose (caused by *Colletotrichum* spp.), black knot (caused by *Apiosporina* spp.), brown rot (caused by *Monilinia* spp.), canker (caused by *Cytospora* spp.), crown and root rot (caused by *Armillaria* spp. and *Fusarium* spp.), fruit rot (caused by *Alternaria* spp., *Penicillium* spp., *Cladosporium* spp. and *Botrytis* spp.), leaf spot (caused by *Blumeriella* spp.) and powdery mildew (caused by *Podosphaera* spp.) (Uyemoto, 2018). In China, cherry leaf spot (Chethana et al., 2019), grey mould (Yin et al., 2018), and trunk disease (Chen et al., 2023a) are common fungal diseases, and other diseases occasionally occur under some conditions. Grey mould disease is particularly severe under greenhouse conditions and during storage, especially in high-humid environments (Elad, 2016). Other fruit diseases, such as brown rot caused by *Monilia* spp. and fruit rot caused by *Sclerotinia sclerotiorum*, were also reported in China (Ruan et al., 2023; Zhao et al., 2023). Trunk diseases on cherry were recognized to be caused by *Botryosphaeria dothidea*, known as gummosis disease (Zhang et al., 2019). Chen et al. (2023) found that *Diaporthe* species also cause branch dieback and gummosis on cherry. Due to its wide distribution in most cherry-growing areas worldwide, cherry leaf spot has been getting more attention in China in recent years. Though *Blumeriella jaapi* is regarded as the causal agent of leaf spot disease in America and Europe (Holb, 2009), the reported pathogens in China are different, which are mainly *Pruniphilomyces circumscissus* (= *Passalora circumscissa*), *Colletotrichum* spp. and *Alternaria* spp. (Chethana, 2019; Sun et al., 2022). The disease causes early defoliation, and in severe cases, eventual death of the tree (Ellis, 2016). Therefore, it is of great significance to identify the main types and pathogens of cherry leaf spot disease in order to maintain sustainable and safe cherry production in China.

1.3.2 Fungal Diseases and Pathogens of the Grapevine

Among numerous reports of grapevine diseases caused by fungi and Oomycetes, anthracnose, bitter rot, Botrytis bunch rot and blight, downy mildew, powdery mildew, Phomopsis cane and leaf spot, ripe rot, white rot, and grapevine trunk diseases occur in most grapevine cultivation regions (Wilcox et al., 2015). Some diseases are caused by common pathogens worldwide, such as downy mildew by *Plasmopara viticola* (Boso et al., 2014), black rot by *Guignardia bidwellii* (Szabó et al., 2023), and bunch rot and blight by *Botrytis cinerea* (Steel et al., 2013), while others are caused by various pathogens in different countries. For example, grapevine anthracnose is usually known to be caused by *Elsinoe ampelina*, while anthracnose was also found to be caused by *Colletotrichum* species with different symptoms in China (Yan et al., 2015; Li et al., 2021). *Coniella vitis* was the main pathogen of white rot in China rather than *Coniella diplodiella*, which was considered to be the causal agent previously (Chethana et al., 2017; Ji et al., 2021). Unlike other diseases caused by specific pathogens, grapevine trunk diseases are a group of diseases caused by multiple fungal pathogens (Mondello et al., 2018). Grapevines can be affected by one or more trunk diseases simultaneously, including Esca complex, Eutypa dieback, Botryosphaeria dieback, black foot and Phomopsis (Diaporthe) dieback caused by different pathogens belonging to *Botryosphaeriaceae*, *Diaporthe*, *Cylindrocarpon*-like fungi and others (Gramaje et al., 2018). Field symptoms have become complex due to the mixed infections caused by different pathogens (Patanita et al., 2022). Grapevine trunk diseases have become a huge threat to the sustainable development of the viticulture and viniculture industries, resulting in reduced yields and limited vineyard lifespans (Hrycan et al., 2020).

1.3.3 Fungal Diseases and Pathogens of Blueberry

As for blueberry diseases, fungal diseases also occur on the whole plants, including fruit rots caused by *Alternaria*, *Colletotrichum*, *Botrytis*, *Diaporthe* and *Phyllosticta* species, Armillaria root rot caused by *Armillaria*, stem blight and dieback caused by Botryosphaeriaceae and pestalotioid fungi, twig blight caused by *Gibbera* and *Diaporthe*, stem canker caused by *Botryosphaeriaceae*, *Fusicoccum*, *Gloeosporium*, *Diaporthe* and *Septoria* taxa, Botrytis blossom blight caused by *Botrytis* spp., Cylindrocladium rot caused by *Calonectria* spp., leaf spot caused by pestalotioid fungi, *Alternaria*, *Exobasidium*, *Septoria* and *Phyllosticta* taxa, and Powdery mildew caused by *Erysiphe* spp. (Araujo et

al., 2023; Polashock et al., 2017; Santos et al., 2022). In China, stem blight, dieback, or canker of blueberry have been frequently observed, as well as leaf spot and fruit rot (Li et al., 2023a; Zhao et al., 2022; Zheng et al., 2023). Pestalotioid fungi and Botryosphaeriaceae species are the causal agents of stem blight and leaf spot (Zhao et al., 2022; Zheng et al., 2023). *Diaporthe* has been reported to cause stem canker, leaf spot and post-harvest rot (Lai et al., 2023; Li et al., 2023b; Yu et al., 2018). Additionally, *Fusarium* species have been reported to cause root rot (Li et al., 2023c). Other common fungal pathogens, such as *Botrytis*, *Calonectria*, *Cylindrocladium* and *Nigrospora*, were also reported on blueberries in China (Luan et al., 2006; Zhang et al., 2019; Chen et al., 2023b; Li et al., 2023a).

1.4 Research Objectives

1.4.1 To investigate the occurrence of diseases of cherry, blueberry and grapevine across different cultivation regions in China

1.4.2 To identify the micro-fungi associated with the main diseases based on morphology and phylogeny analyses

1.4.3 To determine the pathogenic potential of selected fungi through inoculation experiments to assess their impact on crop health

1.4.4 To speculate the relationship between fungi, disease symptoms, isolation source and cultivation region.

1.5 Research Contents

This thesis is divided into five chapters:

Chapter 1 is the general introduction, which provides a comprehensive background on the current status of cherry, grapevine and blueberry cultivation. It presents an overview of plant diseases and fungal pathogens, highlighting the impact of plant diseases, main disease types affecting fruit trees, complexities of fungal pathogen identification, as well as fungal classification from both plant pathology and taxonomy aspects. Additionally, it offers a brief introduction to fungal diseases and pathogens associated with cherry, grapevine and blueberry.

Chapter 2 details the material and methodology used in this study, including field investigations, sample collection and fungal isolation. It also covers DNA extraction, PCR amplification and sequencing, followed by phylogenetic analyses. Additionally, the chapter describes the morphological characterization of fungal isolates and pathogenicity tests conducted on leaves, stems and fruits.

Chapter 3 investigates and identifies fungal species associated with cherry leaf spot disease in China. This verifies the primary *Colletotrichum* species responsible for leaf anthracnose and reports two newly identified types of cherry leaf spot related to *Fusarium* and *Cladosporium*. Additionally, a new host record on cherry, *Neopestalotiopsis rosae*, was described; and the new species *Diaporthe beijingensis* was introduced. Finally, it provides a summary of fungal species associated with cherry leaf spot diseases worldwide.

Chapter 4 provides a comprehensive identification of fungal species associated with grapevine trunk disease across eight provinces in China. It provides the details of the disease symptoms, fungal species, along with their isolation sources, geographical distribution, global records, as well as taxonomic descriptions. Finally, the dominant fungal genera in this study, the distribution of species, and the roles of different fungal groups in the grapevine are discussed.

Chapter 5 presents a comprehensive study on main fungal diseases (fruit rot, leaf spot, stem blight and root rot) of blueberry and associated fungal groups, which provides a list of fungal species recorded on blueberry in this study, the distribution of fungal genera, taxonomy description on important species, and pathogenicity tests on selected fungal species. A list of fungal species associated with blueberry diseases in China is also provided.

Chapter 6 summarizes the key findings of the study, highlighting the major discoveries and research advancements. It also provides recommendations for future research directions in the study of fungal pathogens associated with cherry, grapevine, and blueberry diseases.

CHAPTER 2

MATERIAL AND METHODS

2.1 Field Investigation, Sample Collection and Fungal Isolation

Fungal diseases were investigated at orchards in major cultivation regions in China. Cherry leaf spot disease samples were collected from Beijing, Shandong and Liaoning. Grapevine trunk disease samples were collected from Beijing, Fujian, Hebei, Hubei, Ningxia, Shaanxi, Shanxi and Yunnan. Blueberry disease samples were collected from Fujian, Guizhou, Heilongjiang, Jilin and Liaoning (Figure 2.1).

Figure 2.1 Collection site of cherry, grapevine and blueberry samples in China

Field symptoms of the main diseases were recorded and photographed, and samples with typical symptoms were collected in zip-lock bags with information labels (collection site, variety, temporary sample number). Samples were kept in the box with an ice bag and the stems of leaf samples were wrapped with wet tissue to preserve

moisture. After being brought to the laboratory, leaf and fruit samples were kept in the fridge, wood samples were kept in a cool place, and all samples were processed within 48 h in case the growth of saprobes.

Before isolation, photos of systemic and local symptoms (including section views of wood samples) of the samples were also taken in the lab for further studies. Lesions on samples were checked through the stereomicroscope Nikon SMZ1500 (Nikon, Japan). If fungal spore masses or fruiting bodies were observed on the surface of the lesion, they were picked or scraped using sterile needles to make slides or spore suspensions. Prepared slides were checked using the Nikon E200 compound microscope (Nikon, Japan) to preliminarily speculate the taxa of fungi according to the micromorphology, such as spore characters. If spores are in sufficient quantity, single spore isolation was conducted. Spores were suspended in sterile water, adjusted the concentration to around 1×10^4 spores/mL, and 80–100 mL suspension was added on the surface of water agar (WA) plates and evenly spread. Germinated spores were picked up with a sterilized needle and transferred onto fresh PDA plates. If few spores were observed or no spores in fruiting bodies, diseased samples were kept in high humidity to induce sporulation. For samples without spores and fruiting bodies on the lesion surface, tissue isolation was conducted. Tissues from the junction between diseased and healthy areas were cut into small pieces (5×5 mm) with sterilized scissors or blades, surface sterilized using 75% alcohol for 30 s and 2% NaClO for 2 min, and rinsed three times in sterile water. After drying on the sterilized filter paper, tissues were transferred onto potato dextrose agar (PDA) plates and incubated at 25°C. After 3–5 days of inoculation, colonies with different morphologies were counted, and the hyphal tips of selected colonies were transferred onto fresh PDA plates. After sporulation, single spore isolation was performed using the method mentioned earlier. For some non-sporulating isolates, single hyphae tip isolation was performed, and near-ultraviolet light and plant tissue (pine needle or host tissue) were also used to induce sporulation (Su et al., 2012). Pure cultures were preserved on PDA slopes at 4°C. All isolates obtained in this study were deposited in the culture collection of the Institute of Plant Protection, Beijing Academy of Agriculture and Forestry Sciences (JZB), China. Dry cultures of new species and new geographic or host records were deposited

in the herbarium of the Institute of Plant Protection, Beijing Academy of Agriculture and Forestry Sciences (JZBH), China.

2.2 DNA Extraction, PCR Amplification and Sequencing

Purified isolates were cultured on PDA plates for seven days at 25°C. Fresh mycelia grown on PDA plates were collected into 1.5 mL centrifuge tubes (500 mg), and genomic DNA was extracted using the CTAB (cetyltrimethylammonium bromide) method (Udayanga et al., 2012) or TIANcombi DNA Lyse and Det PCR Kit (Tiangen Biotech Co., Ltd., Beijing, China). Polymerase chain reactions (PCR) were performed in C1000 Touch™ Thermal Cycler to amplify different gene regions with the primers shown in Table 2.1: internal transcribed spacer region (ITS), partial translation elongation factor 1-alpha (*tef1*), β -tubulin (*tub2*), RNA polymerase II second largest subunit (*rpb2*), 28S large subunit of nuclear ribosomal RNA (LSU), histone H3 (*his3*), actin (*act*), calmodulin (*cal*), glyceraldehyde 3-phosphate dehydrogenase (*gapdh*), chitin synthase (*chs*) and heat shock protein 60 (*hsp60*). The 50 μ L volume of the PCR mixture includes 44 μ L of 1 \times Taq PCR Mix (TransGen Biotech, Beijing, China), 2 μ L of each forward and reverse primer (Sangon Biotech, Shanghai, China), and 2 μ L of DNA template. The PCR conditions were as follows: initial denaturation for 3 min at 95°C, followed by 34 cycles of denaturation for 30 s at 95°C, annealing for 30 s, 1 min elongation at 72°C, and final extension for 10 min at 72°C. The annealing temperatures for different primers were noted in Table 2.1. The PCR products were examined in 1.5% agarose gel under UV light after staining with ethidium bromide and sequenced at SinoGenoMax Co., Ltd. (Beijing, China). Chromatograms of generated sequences were checked with BioEdit 7.0.9.0 to confirm sequence quality. Eligible sequences of the internal transcribed spacer (ITS) region were compared with sequences in GenBank of the National Centre for Biotechnology Information (NCBI) using the BLAST tool (<https://blast.ncbi.nlm.nih.gov/Blast.cgi>). Other gene loci were then amplified according to the resulting genus.

2.3 Phylogenetic Analysis

Reference sequences for phylogenetic analyses were downloaded from the GenBank, NCBI (National Centre for Biotechnology Information), following the relevant literature (Table 2.2). Each dataset was aligned in MAFFT v. 7 (<https://mafft.cbrc.jp/alignment/server/>) (Kato et al., 2019) and manually adjusted in BioEdit v7.0.9.0. where necessary, and sequences of different gene regions were trimmed by trimAl (Capella-Gutiérrez et al., 2009), then aligned gene regions were concatenated using BioEdit v7.0.9.0.

Phylogenetic analyses of alignments were conducted using maximum likelihood (ML) and Bayesian inference (BI) analysis. The ML analyses were implemented on the combined alignment through the tool RAXML-HPC2 on XSEDE (v.8.2.12) (Stamatakis et al., 2008; Stamatakis, 2014) in the online platform CIPRES Science Gateway (<https://www.phylo.org/portal2>) (Miller et al., 2010). The model of evolution GTR + I + G with 1000 nonparametric bootstrapping iterations were applied. Bayesian posterior probabilities (BYPP) were evaluated using MrBayes v3.2.7 based

on the Markov Chain Monte Carlo sampling (BMCMC), and different evolutionary models were selected using MrModeltest v. 3.7. For the combined dataset, six simultaneous Markov chains were run for 2,000,000 generations and trees were sampled at every 1000th generation. The first 25% of the generated trees were discarded, and the remaining 75% was used to calculate posterior probabilities (PP) of the majority rule consensus tree (Ronquist & Huelsenbeck, 2003).

Phylogenetic trees were visualized in FigTree v. 1.4.0 (Rambaut, 2023) and edited in Microsoft Office PowerPoint 2016 and Adobe Illustrator 2020. Sequences generated in this study were deposited in GenBank.

2.4 Morphological Characterization

The morphological characteristics of each species were examined. For cultural features, mycelial discs (5 mm in diam.) were taken from the growing edge of 6-day-old cultures in triplicate, transferred to fresh plates of PDA, and incubated in the dark at 25°C. The shape, color and density of colonies were recorded. Colony colors were recorded following Rayner (1970), and colony diameters were measured. To observe micromorphological characters, isolates were cultured on PDA, carnation leaf agar (CLA) (for *Fusarium*), pine needle agar (PNA), as well as host tissues on agar (Su et al., 2012). After sporulation, the micromorphology of fungal structures was observed using Axio 506 color Imager Z2 photographic microscope (Carl Zeiss Microscopy, Oberkochen, Germany), and photographs and measurements were taken with ZEN Pro 2012 (Carl Zeiss Microscopy). Pictures were processed and combined into photo plates using Adobe Photoshop CS6 Extended (V13.1.2). Description and photo plates were provided for the new species and new records.

2.5 Pathogenicity Test

2.5.1 Cherry Leaf Spot

Pathogenicity was tested by inoculating detached leaves with spore suspension. Representative isolates of each species were cultured on PDA at 25°C until sporulation.

Tender, healthy-looking leaves of *P. avium* were collected from Tongzhou Experimental Station for Cherries, Beijing Academy of Forestry and Pomology Sciences, Beijing, China. Leaves were surface-sterilized with 75% ethanol for 30 s, rinsed three times with sterile water and air-dried on sterilized filter paper. Fungal spores produced on the cultures were collected into 1.5 mL centrifuge tubes using sterilized toothpicks. Spore suspensions were prepared in sterile water and adjusted to a concentration of 1.0×10^6 conidia/mL and determined with a haemocytometer. Spore suspensions were symmetrically inoculated on either side of the main leaf veins, with one side pierced by four small holes made with a sterile insect mounting needle (wound) and the other side remained unwound. Five leaves were inoculated for each isolate in plastic boxes maintained at 25°C and 80% relative humidity and a 12/12 h light/dark cycle. Control leaves were treated with sterilized water. Inoculated plants were maintained in a greenhouse at 25°C under a light/ dark cycle. Experiments were carried out three times. Disease incidence (%) [(symptomatic sites/total inoculated sites) \times 100%] was calculated, and lesion diameters were measured after the appearance of symptoms. Data was subjected to two-way analysis of variance using the software IBM SPSS Statistics v21 to determine the significance of the differences. Means of different species from the pathogenicity test were separated using the least significant difference test at a $P = 0.05$ level. Symptoms were observed every day. Koch's postulates were confirmed by re-isolating the inoculated fungi, which were identified based on cultural and morphological characters, as well as molecular characteristics.

2.5.2 Blueberry Fruit Rot

Pathogenicity tests were conducted on detached fruits using spore suspension of representative isolates. Conidia were collected from fruiting bodies on the cultures, dispersed in sterile water, and adjusted to 1×10^6 conidia per mL using a hemocytometer, and 0.02% Tween-20 was added to increase surface activity. Fresh, healthy, and unwounded blueberry fruits were surface-disinfested in 75% ethyl alcohol for 2 min, rinsed three times with sterile water, and then air-dried on filter paper. Fruits were placed at the bottom of 9 mm petri dishes with moist filter paper and inoculated with 20 μ L of conidial suspension on the fruit. The experiment was conducted on eight fruits for each isolate and repeated three times. The same amount of sterile water was dropped on the fruits as the control. Plates were placed in the plastic box covered with plastic

wrap to maintain the humidity and incubated at 25°C. Inoculated fruits were observed daily until they showed symptoms and photographed with a camera and stereomicroscope. To fulfil Koch's postulate, fungi were re-isolated from the diseased site and identified by morphological characters.

2.5.3 Blueberry Stem Blight

Pathogenicity tests were conducted on one-year-old green shoots of blueberry. One isolate from each of the three species was selected and inoculated onto fifteen shoots, respectively. Mycelium plugs (4 mm) were made by a disinfected hole puncher from the margin of a 5-day-old colony. The green shoots were cut to 30 cm in length and surface sterilized using 75% ethyl alcohol. Wounds with a 4 mm diameter and 2 mm depth were created using a hole puncher on the internode. Mycelium plugs were placed on the wounds and wrapped with sealing film. PDA plugs were used as controls. Inoculated green shoots were inserted into small pots with moist soil and incubated in the greenhouse at 25°C and 100% humidity; after 48 h, the sealing film was removed, and the humidity was maintained at 80%. Inoculation results were observed after three weeks, and lesions were photographed and measured. Koch's postulate was confirmed by re-isolating the inoculated fungus, which was identified based on morphological characters.

CHAPTER 3

IDENTIFICATION OF FUNGAL SPECIES ASSOCIATED WITH CHERRY LEAF SPOT DISEASE

3.1 Introduction

3.1.1 An Overview of Cherry Leaf Spot Disease

Cherry leaf spot (CLS) is a common, serious disease of sweet cherry worldwide (Holb, 2009). Leaf spots caused by various fungal pathogens lead to early defoliation and eventual death of the tree (Chethana et al., 2019). Capacity for photosynthesis in leaves is affected by cherry leaf spot, and the early leaf defoliation during summer weakens the trees and increases their susceptibility to frost, ultimately leading to considerable yield losses and a reduction of their quality (Gruber et al., 2012; Ellis, 2016). Leaf spot can be particularly damaging in severe cases; it has been reported in Israel to cause a loss of up to 40% of cherry yield (Sztejnberg, 1986), and the disease incidence rate in China can exceed 90% in severe cases (Liu, 2012). Humidity is an important factor affecting the occurrence of leaf spot disease, wet weather can cause all the leaves of infected orchards to fall off in mid-June without applying medicine (Andersen et al., 2018).

The disease was first reported in America in 1878 and later reported in Europe and other countries (Holb, 2009). *Blumeriella jaapi* was identified as the most common organism in many countries and caused brown spots with whitish-pink masses of spores on the infected leaves (Wharton et al., 2003). In the later stage, the lesions expanded and fused to form a large spot, or the middle part fell off to form a shot hole. Leaves exhibit chlorosis and fall off (Ellis, 2016). The fungi overwinter on the diseased leaves with the stroma, produce ascospores in spring, and release ascospores under humid conditions at the flowering stage for initial infection. Conidial reinfection occurs in late spring and persists into autumn (Garcia, 1993). Other studies have shown that pathogens may also overwinter on dormant buds as the primary infection source

(Joshua & Mmbaga, 2015). Though *B. jaapi* is the main pathogen in America and Europe, it has not been reported in China.

Species belonging to Mycosphaerellaceae are also causal agents of cherry leaf spot, with a long history. In 1886, Saccardo isolated *Cercospora circumscissa* from cherry leaves in Italy for the first time, and reported its sexual morph *Mycosphaerella cerasella*, in 1902. In 1974, leaf spot disease caused by *C. circumscissa* was widespread in Israel. The symptom of *Cercospora* leaf spot was 4-5 mm in diameter, with a light brown centre and reddish-brown edges. Lesions can occur on both the upper and lower surfaces of the leaves, and often form shot-hole or combine into large lesions in the later stages (Sztejnberg, 1986). Afterwards, *Passalora circumscissa* was isolated from cherry leaves in South Africa (Crous & Braun, 1996), and *Pseudocercospora pruni-persicicola* was reported in Korea in 2014 (Choi et al., 2014). In China, *Mycosphaerellaceae* are associated with CLS, including *Cercospora circumscissa*, *Pseudocercospora circumscissa* and *Passalora circumscissa*, with *Mycosphaerella cerasella* as the sexual morph (Sun et al., 2014). Crous et al. (2020) re-classified *Cercospora circumscissa*, *Passalora circumscissa* and *Mycosphaerella cerasella* as a new combination, *Pruniphilomyces circumscissus*, and isolated the species from the leaf spot of sour cherry. In addition to the two typical pathogens, there are other records of pathogenic fungi infecting cherry leaves, such as *Alternaria alternata* reported in Greece, causing enlarging blackish leaf spots (Thomidis & Tsipouridis, 2006); and *Colletotrichum acutatum* reported in Norway as a latent pathogen (Børve & Stensvand, 2008).

In the early studies on cherry leaf spots, fungal identifications were only based on the field experience of morphological characters. With the development of molecular techniques, mycologists have suggested that a polyphasic approach is necessary for identification of fungi at the species level. In this way, phytopathogens were identified based on morphological characteristics, phylogenetic analyses and pathogenicity tests, which enabled the identification to be more accurate (Crous et al., 2015; Chethana et al., 2019). In recent years, more fungal species associated with CLS, especially *Alternaria* and *Colletotrichum* species, have been accurately identified in China (Chethana et al., 2019; Zhou et al., 2023).

3.1.2 Common Fungal Pathogens Associated with Cherry Leaf Spot in China

3.1.2.1 *Pruniphilomyces circumscissus*

Pruniphilomyces circumscissus (syn. *Cercospora circumscissa*, *Pseudocercospora circumscissa*, *Passalora circumscissa* and *Mycosphaerella cerasella*) was previously recognized as the dominant pathogen of cherry leaf spot disease in China. Guo and Liu (1992) reported the species (as *Pseudocercospora circumscissa*) from sour cherry. Subsequently, *Cercospora circumscissa*, *Pseudocercospora circumscissa* and the sexual morph *Mycosphaerella cerasella* were reported to cause leaf spot disease, termed brown spot, on sweet cherry (Shao, 1995; Zhang, 2010). However, no morphological and molecular evidence were provided in these records. In 2012, Liu et al., identified the pathogen of brown spot as *Passalora circumscissa* by morphological characterization, and Sun et al. (2017) identified *Passalora circumscissa* through morphological identification and ITS analysis. Though Crous et al. (2020) have proposed the new combination *Pruniphilomyces circumscissus* to accommodate these species, *Passalora circumscissa* was still used in recent research (Ma et al., 2022; Sun et al., 2022).

3.1.2.2 *Alternaria* spp.

During an investigation on black spot disease, a prevalent leaf disease in Gansu Province in 2001–2002, the pathogen was identified as *Alternaria cerasi* by morphological characters (Zhu & Chang, 2004). Zhao et al. (2013) isolated *A. alternata* from cherry fruits with black spot symptoms in Liaoning Province, and inoculated on cherry leaves, resulting in weak pathogenicity. Later, *A. alternata* was frequently isolated from Beijing City, Gansu Province and Qinghai Province (Chethana et al., 2019; Liu et al., 2020). In addition, *A. tenuissima* was reported in both Gansu and Qinghai Provinces (Liu et al., 2020). Chethana et al. (2019) introduced two new species *Alternaria prunicola* and *Alternaria pseudo-eichhorniae*., with *A. prunicola* as the main CLS pathogen in Beijing.

3.1.2.3 *Colletotrichum* spp.

The genus *Colletotrichum* ranked eighth among the top 10 fungal plant pathogens worldwide, causing many diseases, especially anthracnose, in a wide range of herbaceous or woody plants (Dean et al., 2012). However, reports of *Colletotrichum* associated with cherry leaf spot in China have just appeared in recent years. Chethana

et al. (2019) identified *C. aenigma* and *C. pseudotheobromicola* associated with cherry leaf spot disease in Beijing, which exhibited a higher level of virulence than the main pathogen *A. prunicola* in the study. In 2020, *Colletotrichum* species were isolated from cherry leaves in Qinghai Province, but were not identified to species level. Tang et al. (2021) reported *C. fructicola* causing cherry anthracnose in Zhejiang Province. The descriptions of symptoms of anthracnose leaf spot were similar, which appeared as small, dark red or purple pinpoint lesions on the leaves, and later the lesions enlarged to form dark brown or red brown circular lesions (Chethana et al., 2019; Liu et al., 2020; Tang et al., 2021). Zhou et al. (2023) further divided three symptom types of anthracnose leaf spot (brown spot, purple spot and leaf blight) through investigation in four provinces in China, and identified thirteen species. It was interesting that lesions showed different characters when infected by different *Colletotrichum* species, and the pathogenicity test on living plants reproduced the lesion consistent with the field symptoms.

3.1.2.4 Didymellaceae species

In 2019, Chethana et al., reported four Didymellaceae species associated with cherry leaf spot in Beijing, including *Nothophoma quercina* and *Stagonosporopsis citrulli* and two new species *Epicoccum pseudokeratinophilum* and *Nothophoma pruni*. The species showed weak virulence in the pathogenicity test, thus possible be the secondary pathogen of cherry leaf spot.

3.1.2.5 Other pathogens

Some fungi associated with other diseases of cherry were also found to cause cherry leaf spot. *Botryosphaeria dothidea*, the causal agent of cherry gummosis disease, was reported to cause large brown spots on cherry leaves, leading to leaf chlorosis, blight or defoliation (Zhou et al., 2021); *Diaporthe eres* was recorded on cherry early, while no detailed information was provided (Dai et al., 1979). Zhou et al. (2022) reported a cherry leaf spot disease showing brownish-grey lesions surrounded by yellowish halo rings caused by *D. eres*, as well as *D. sojae*.

In conclusion, though more studies on cherry leaf spot are emerging in recent years, the knowledge on the disease is still limited. In contrast to *Blumeriella jaapi*, the dominant causal agent of the disease in most European and American countries, CLS pathogens seem to be more diverse in China. However, previous fungal

identification on cherry leaf spot was usually based on morphological characters and sequences of the ITS region, which may cause inaccurate identification results; and latest research on CLS pathogens are still very few compared with other important fruit crops. Therefore, it is necessary to continue the investigation and fungal identification of cherry leaf spot disease.

3.2 Results

During the investigation of cherry leaf spot disease, different symptoms of cherry leaf spot were observed, which led to the leaf chlorosis or defoliation in the late stages (Figure 3.1).

According to the result of previous publications and data from the lab, *Alternaria*, *Colletotrichum*, *Cladosporium*, Didymellaceae species, and *Fusarium* are the top five groups of fungi associated with cherry leaf spot. *Alternaria* associated with CLS have been studied in different regions in China (Chethana et al., 2019; Liu et al., 2020; Yang et al., 2020), and Didymellaceae species were found to be weakly pathogenic (Chethana et al., 2019). Therefore, this study was focused on the other three genera. Though *Colletotrichum* species causing anthracnose leaf spot have been comprehensively identified (Chethana et al., 2019; Zhou et al., 2023), a re-investigation and identification were conducted to compare the dominant species of *Colletotrichum* with previous studies.

Figure 3.1 Symptoms of cherry leaf spot disease in the field

3.2.1 *Colletotrichum* Species Causing Cherry Leaf Spot Disease in Beijing, China

3.2.1.1 Sampling and fungal isolation

In 2021, thirteen anthracnose leaf spot samples of sweet cherry were collected from Haidian, Fangshan and Tongzhou District, Beijing, China (Figure 3.2). The symptoms present circular to subcircular, brown spots with dark-brown or purple margins, and some showed leaf blight with semicircular or irregular brown necrotic lesions at the leaf margin. The symptoms were consistent with the previous description (Zhou et al., 2023). Eighteen isolates were generated by direct single-spore isolation or tissue isolation.

Note A–C leaf symptoms in the field. D–F leaf spot samples.

Figure 3.2 Anthracnose cherry leaf spot

3.2.1.2 Molecular and morphological identification

According to the BLAST results of the ITS region, all isolates belong to the *Colletotrichum gloeosporioides* species complex. The multi-locus phylogenetic tree of *C. gloeosporioides* species complex was constructed based on *act*, *tub2*, *cal*, *chs-1*, *gapdh* and ITS, with *C. boninense* (CBS 123755) as the outgroup (Figure 3.3). Eight isolates clustered with the ex-type of *C. gloeosporioides* (IMI 356878) with 100% ML bootstrap support value and 1.00 BYPP. Eight isolates clustered with the ex-type of *C. fructicola* (ICMP 18646) with 99% ML bootstrap support value and 1.00 BYPP. Two isolates clustered with the ex-type of *C. aenigma* (ICMP 18608) with 97% ML bootstrap support value and 1.00 BYPP.

Figure 3.3 Phylogenetic tree generated by maximum likelihood analysis (RAxML) of *Colletotrichum gloeosporioides* species complex based on the combined *act*, *tub2*, *cal*, *chs-1*, *gapdh* and ITS sequence data

Figure 3.3 The tree is rooted with *C. boninense* (CBS 123755). The best scoring RAxML tree with a final likelihood value of -4987.801452 is presented. The matrix had 738 distinct alignment patterns, with 0.90% of undetermined characters or gaps. Estimated base frequencies were as follows: A = 0.22653, C = 0.29987, G = 0.24843, T = 0.22678; substitution rates AC = 1.00000, AG = 3.46970, AT = 1.00000, CG = 1.00000, CT = 5.77541, GT = 1.00000; gamma distribution shape parameter $\alpha = 0.40254$. ML bootstrap support values $\geq 50\%$ and Bayesian posterior probabilities (BYPP) ≥ 0.95 are shown near

the nodes. The scale bar indicates 0.02 changes per site. The ex-type strains are in bold, and isolates from the current study are in red.

Morphologically, the three species conformed to the description of ex-type and previous isolates from CLS of *C. gloeosporioides*, *C. fructicola* and *C. aenigma* (Cannon et al., 2008; Prihastuti et al., 2009; Weir et al., 2012; Zhou et al., 2023) (Figure 3.4). *Colletotrichum* species within a species complex may share similar morphology, and morphological characters of a species can be changed by subculturing, different conditions of growth and differences between strains, which are insufficient to distinguish species within a species complex. The definition of species is thus mainly based on multi-gene phylogenies (Weir et al., 2021).

Therefore, *Colletotrichum* isolates generated in this study are identified as *C. gloeosporioides* (8 isolates), *C. fructicola* (8 isolates) and *C. aenigma* (2 isolates), which are also the top three groups in the previous study (Zhou et al., 2023).

Figure 3.4 Morphological characteristics of *Colletotrichum* species isolated from cherry leaf spot

Figure 3.4 A Front (left) and back (right) views of the 4-day-old colony of *C. gloeosporioides*. B Front (left) and back (right) views of the 4-day-old colony of *C. fructicola*. C Front (left) and back (right) views of the 4-day-old colony of *C. aenigma*. D Conidiomata of *C. gloeosporioides*. E Conidiomata of *C. fructicola*. F Conidiomata of *C. aenigma*. G Conidia of *C. gloeosporioides*. H Conidia of *C. fructicola*. I Conidia of *C. aenigma*. Scale bars: G–I = 10 μm .

3.2.1.3 Pathogenicity test

Three days post inoculation, all *Colletotrichum* species were pathogenic to detached cherry leaves (Figure 3.5). Leaves inoculated with *C. gloeosporioides* and *C. fructicola* showed dark brown lesions on both wounded and unwounded side, while leaves inoculated with *C. aenigma* only shown lesions in the wounded side. No symptoms were observed on the control leaves. The fungi were re-isolated from the lesions successfully and identified using morphology and molecular analyses.

Figure 3.5 Pathogenicity test of *Colletotrichum* species on detached cherry leaves (cv. Caihong) three days post inoculation

Figure 3.5 A–C Detached leaves inoculation of *C. gloeosporioides*, *C. fructicola* and *C. aenigma*, respectively. Left side of the leaf was unwounded before inoculation, right side was wounded. D Control.

3.2.1.4 Summary

Colletotrichum is a common pathogen on cherry associated with leaf spot disease. In this study, twenty *Colletotrichum* isolates from cherry leaf spot in Beijing were identified as *C. gloeosporioides*, *C. fructicola* and *C. aenigma*, which have been reported

by Zhou et al. (2023) as the top three species in terms of isolate number. Current results verified the conclusion that the three species are the main pathogens causing anthracnose leaf spot. In the pathogenicity assay, *C. gloeosporioides* and *C. fructicola* were pathogenic to both wounded and unwounded leaves, while *C. aenigma* could only cause lesions on wounded leaves. This result is different from previous studies that *C. aenigma* exhibited strong pathogenicity (Zhou et al., 2023), which may be influenced by the cherry cultivar and virulence difference between fungal isolates.

3.2.2 *Fusarium* Species Causing Cherry Leaf Spot Disease in China

3.2.2.1 Symptom observation, sample collection and fungal isolation

From 2019 to 2020, fifteen cherry leaf spot samples were collected from cherry orchards (open field) in Beijing, Liaoning and Shandong Provinces in China, with the following symptoms, (1) small purple-brownish spots which may merge with expansion (Figure 3.6. A–B); (2) circular or irregular brownish grey necrotic lesions with dark brown margin (Figure 3.6. C–D). Twenty-four *Fusarium* isolates were obtained by tissue isolation, among which thirteen were from Beijing, nine from Shandong and two from Liaoning (Table 3.1).

Note A, B symptom type 1. C, D symptom type 2

3.2.2.2 Molecular characterization and phylogenetic analysis

The ITS sequences of isolates showed 100% similarity to *Fusarium* spp. based on BLAST analysis. Phylogenetic trees of *Fusarium incarnatum-equiseti* species complex (FIESC), *Fusarium lateritium* species complex (FLSC), *Fusarium fujikuroi*

species complex (FFSC) and *Fusarium oxysporum* species complex (FOSC) were constructed using combined sequence alignment. The sequences were deposited in GenBank, and accession numbers were obtained.

Phylogenetic analysis of FIESC was constructed based on the combined *CaM*, *rpb2* and *tef1* multi-locus dataset, with *Fusarium concolor* (CBS 961.87) as the outgroup taxon (Figure 3.7). Both maximum likelihood and Bayesian analyses resulted in the same topology. Among the ninety-six fungal isolates in the dataset, fifteen were from the current study. Seven isolates clustered with *F. luffae* in two branches with 67% ML bootstrap and 1.0 BYPP, and 70% ML bootstrap, five clustered with *F. compactum* with 81% ML bootstrap and 0.99 BYPP, two clustered with *F. citri* with 63% ML bootstrap and 0.95 BYPP, and one isolate with *F. ipomoeae* with 99% ML bootstrap and 1.0 BYPP.

Phylogenetic analysis of FLSC was constructed based on the combined *rpb2*, *tef1* and *tub2* multi-locus dataset, with *Fusarium buharicum* (CBS 796.70) as the outgroup taxon (Figure 3.8). Both maximum likelihood and Bayesian analyses resulted in the same topology. Six isolates clustered with *F. lateritium* with 94% ML bootstrap and 1.0 BYPP.

Phylogenetic analysis of FFSC was constructed based on the combined *tef1*, *rpb2*, *tub2* and *CaM* multi-locus dataset, with *Fusarium nirenbergiae* (CBS 744.97) as the outgroup taxon (Figure 3.9). Both maximum likelihood and Bayesian analyses resulted in the same topology. Two isolates clustered with *F. nygamai* with 100% ML bootstrap and 1.0 BYPP.

Phylogenetic analysis of FOSC was constructed based on the combined *rpb2*, *tef1* and *tub2* multi-locus dataset, with *Fusarium foetens* (CBS 120665) and *Fusarium udum* (CBS 177.31) as the outgroup taxa (Figure 3.10). Both maximum likelihood and Bayesian analyses resulted in the same topology. One isolate clustered with *F. curvatum* with 69% ML bootstrap and 1.0 BYPP.

Figure 3.7 Phylogenetic tree generated by maximum likelihood analysis (RAxML) of FIESC based on the combined *CaM*, *rpb2* and *tef1* sequence data

Figure 3.7 The tree is rooted with *Fusarium concolor* (CBS 961.87). The best scoring RAxML tree with a final likelihood value of -11974.052080 is presented. The matrix had 701 distinct alignment patterns, with 7.69% of undetermined characters or gaps. Estimated base frequencies were as follows: A = 0.258901, C = 0.260331, G = 0.245699, T = 0.235069; substitution rates AC = 1.002698, AG = 4.065670, AT =

1.349366, CG = 0.882966, CT = 10.506153, GT = 1.000000; gamma distribution shape parameter $\alpha = 0.751525$. ML bootstrap support values $\geq 50\%$ and Bayesian posterior probabilities (BYPP) ≥ 0.95 are given near the nodes. The scale bar indicates 0.03 changes per site. Isolates belong to this study are given in red.

Figure 3.10 The tree is rooted with *Fusarium foetens* (CBS 120665) and *Fusarium udum* (CBS 177.31). The best-scoring RAxML tree with a final likelihood value of -4987.801452 is presented. The matrix had 199 distinct alignment patterns, with 0.90% of undetermined characters or gaps. Estimated base frequencies were as follows: A = 0.251044, C = 0.269288, G = 0.238899, T = 0.240769; substitution rates AC = 1.155437, AG = 2.887244, AT = 0.424595, CG = 0.728892, CT = 5.651969, GT = 1.000000; gamma distribution shape parameter $\alpha = 1.022063$. ML bootstrap support values $\geq 50\%$ and Bayesian posterior probabilities (BYPP) ≥ 0.95 are given near the nodes. The scale bar indicates 0.02 changes per site. Isolates belonging to this study are given in red.

3.2.2.3 Morphological observation

Morphological characteristics were shown in Figure 3.11, Table 3.2 and Table 3.3. Based on cultural and morphological characters, *Fusarium* isolates were consistent with *F. compactum*, *F. ipomoeae*, *F. luffae*, *F. citri*, *F. nygamai*, *F. lateritium*

and *F. curvatum* as previously described (Leslie & Summerell, 2006; Wang et al., 2019; Lombard et al., 2019).

Table 3.2 Characteristics of colonies of *Fusarium* fungi cultivated on PDA

Species	Average diameter of colony (range)	Type and colour of aerial mycelium	Reverse pigmentation
	on 5 d, mm		
<i>F. compactum</i>	79–85	White mycelia with brown pigments produced in the agar	White to pale yellow
<i>F. ipomoeae</i>	59–65	Colony margin lobate, pinkish white	Pale pink
<i>F. luffae</i>	67–73	Aerial mycelia dense, colony white	White to pale yellow
<i>F. citri</i>	78–80	Aerial mycelia dense, colony margin entire, white	Pinkish white
<i>F. nygamai</i>	53–56	Mycelia violet, with violet pigments produced in the agar	Violet with white margin
<i>F. lateritium</i>	45–54	Mycelia sparse, pale orange or pale pink	Pale orange or pale pink with white margin
<i>F. curvatum</i>	68–70	Mycelia violet, with violet pigments produced in the agar	Dark violet

Table 3.3 Description of conidia of *Fusarium* fungi cultivated on CLA

Species	Macroconidia		Microconidia	
	Shape, number of septa	Average size (range)	Shape, number of septa	Average size (range)
<i>F. compactum</i>	Strong dorsiventral curvature, apical cell elongate and tapering that is often needle like in appearance, basal cell foot-shaped, usually 5-septate	43.04–62.05 × 4.02–5.13 µm (avg.=54.08 × 4.50 µm, n=50)	Not observed	
<i>F. ipomoeae</i>	Dorsiventral curvature, smooth, hyaline, apical cell hooked to tapering, basal cell foot-shaped. Usually 5-septate	40.72–66.64 × 3.67–4.65 µm (avg.=56.60 × 4.16 µm, n=50)	Not observed	

Table 3.3 (continued)

Species	Macroconidia		Microconidia	
	Shape, number of septa	Average size (range)	Shape, number of septa	Average size (range)
<i>F. luffae</i>	Falcate, slender, slightly curved, smooth to slightly rough, hyaline, apical cell blunt or hooked, basal cell barely notched, 3–5-septate	26.18–42.88 × 3.75–4.69 μm (avg.=33.69 × 4.17 μm, n=50)	Not observed	
<i>F. citri</i>	Falcate, hyaline, apical cell papillate to hooked, basal cell distinctly notched to foot-shaped, 3–5-septate	24.23–48.42 × 4.05–5.39 μm (avg.=36.54 × 4.86 μm, n=50)	Not observed	
<i>F. nygamai</i>	Slender, thin walled, hyaline, straight to slightly curved, apical cell short and tapered, basal cell notched or foot-shaped, usually 3-septate	21.08–36.30 × 2.36–3.91 μm (avg.=25.81 × 2.36 μm, n=30)	Oval to elliptical, usually 0-septate	10.06–16.18 × 2.23–3.86 μm (avg.=12.88 × 3.02 μm, n=30)
<i>F. lateritium</i>	Falcate to relatively straight, with parallel walls, apical cell hooked or beaked, basal cell foot-shaped or notched, 3–5-septate, usually 5-septate	38.81–59.69 × 4.31–5.60 μm (avg.=49.10 × 4.88 μm, n=50)	Not observed	

3.2.2.4 Pathogenicity test

Three days post inoculation, all *Fusarium* isolates were pathogenic to **detached** cherry leaves, resulting in lesions similar to the disease symptoms observed in the field (Figure 3.12). The disease incidences [(symptomatic sites/ total inoculated sites) × 100%] and lesion diameter of wounded and unwounded leaves of each species are reported in Table 3.4. No symptoms were observed on the control leaves. According to the result, *F. compactum*, *F. luffae* and *F. ipomoeae* were the most aggressive and caused lesion diameters of more than 10 mm. The other species were relatively less virulent, with lesion diameters varying from 7 mm to 10 mm, and lesion diameters did not differ significantly. The disease incidence of wounded leaves was slightly higher than that of unwounded leaves, while unwounded leaves of some species appeared to form larger lesion diameters. The fungi were re-isolated from the lesions successfully and identified using morphology and molecular analyses.

Figure 3.12 The pathogenicity test of *Fusarium* spp. on detached cherry leaves (cv. 'Tieton') three days post inoculation

Figure 3.12 A–G Detached leaves inoculation of *F. luffae*, *F. lateritium*, *F. compactum*, *F. nygamai*, *F. citri*, *F. ipomoeae* and *F. curvatum*, respectively. Left side of the leaf was wounded before inoculation, right side was unwounded. H Control.

Table 3.4 Disease incidence and lesion diameter of inoculated leaves 3 days post inoculation

Species	Disease incidence (%)		Lesion diameter (mm)	
	Wounded	Unwounded	Wounded	Unwounded
<i>F. compactum</i>	95	95	13.5 ± 0.3 a	14.0 ± 0.3 a
<i>F. ipomoeae</i>	95	75	11.8 ± 0.3 ab	12.8 ± 0.3 a
<i>F. luffae</i>	100	95	12.8 ± 0.4 ab	14.5 ± 0.5 a
<i>F. citri</i>	100	75	8.3 ± 0.1 b	8.8 ± 0.1 b
<i>F. nygamai</i>	100	95	8.3 ± 0.1 b	7.5 ± 0.1 b
<i>F. lateritium</i>	80	90	9.3 ± 0.1 ab	7.0 ± 0.2 b
<i>F. curvatum</i>	100	100	10.0 ± 0.1 ab	7.5 ± 0.1 b

Notes lowercase letters indicate the significant differences for lesion diameters ($p < 0.05$).

3.2.2.5 Summary

A new type of leaf spot disease was reported, with purplish-brown circular lesions. Twenty-four *Fusarium* isolates were identified as seven species, belonging to four species complexes. Except for *F. lateritium* that has been reported as the pathogen causing trunk diseases in Australia (Cook & Dubé, 1989), the other six species are new host records on cherry. *Fusarium compactum* had been regarded as a saprophyte, while being reported as the pathogen of corm and root rot of banana, a fatal canker on Italian cypress, and a wilt and root rot of peanuts (Frisullo et al., 1994; Madar et al., 1996; Saleh et al., 1997). *Fusarium ipomoeae*, *F. luffae* and *F. citri* were introduced in the study reported from *Fusarium incarnatum-equiseti* complex from China (Wang et al., 2019). Afterwards, *F. ipomoeae* was reported to cause leaf spots on peanut and *Bletilla striata* (Xu et al., 2021; Zhou et al., 2021), *F. luffae* was reported to cause fruit rot on muskmelon in China (Zhang et al., 2022), and *F. citri* was initially isolated from *Citrus* (Wang et al., 2019). *Fusarium nygamai* was first observed on a basal stalk and root rot

of grain sorghum (Trimboli & Burgess, 1985) and can also cause root rot on other crops including cotton, maize, millet, rice and sorghum (Leslie & Summerell, 2006). *Fusarium lateritium* can cause wilt, tip or branch dieback, or cankers on many woody trees and shrubs, including some important fruit trees and coffee (Leslie & Summerell, 2006). The pathogenicity test showed that the analysed strains of all species could produce lesions on detached cherry leaves, and specifically, *F. compactum*, *F. luffae* and *F. ipomoeae* showed relatively high virulence. Therefore, *Fusarium* was proven to be a pathogen of cherry leaf spots in China.

3.2.3 Morphological and Molecular Characterization of *Cladosporium* Species On Sweet Cherry in Beijing, China

3.2.3.1 Sample collection and isolation

A total of 21 isolates were obtained from leaf samples exhibiting leaf spot symptoms in Tongzhou, Fangshan and Haidian districts, Beijing. The leaf spots appear as dark pinpoint lesions, which enlarge to brown spots. As the disease progresses, some lesions merge and become irregular blights, and the diseased area becomes yellow (Figure 3.13).

Note A Symptoms in the field. B Diseased cherry leaf sample.

Figure 3.13 Symptoms of *Cladosporium* cherry leaf spot

3.2.3.2 Phylogenetic analysis

The phylogenetic tree comprised 75 taxa with *Toxicocladosporium banksiae* (CBS 128215) as the outgroup. The best-scoring RAxML tree is shown in Figure 3.14 with a final ML optimization likelihood value of -8376.206813. The matrix had 377 distinct alignment patterns, with 4.98% of undetermined characters or gaps. Estimated base frequencies are as follows: A=0.226153, C=0.294242, G=0.248026, and T=0.231579; substitution rates AC= 2.599833, AG= 5.856880, AT= 2.798124, CG= 1.716334, CT=9.962494, and GT=1.000000; proportion of invariable sites I= 0.574301, gamma distribution shape parameter α =0.595053. The Bayesian analysis resulted in 15,000 trees after 2,000,000 generations. The ML and BI trees were similar in topology and did not differ significantly. The 21 isolates from this study clustered within six clades as *C. anthropophilum*, *C. asperulatum*, *C. cladosporioides*, *C. ramotenellum*, *C. rectoides* and *C. tenuissimum*. The sequences generated in this study were deposited in GenBank.

Figure 3.14 Phylogenetic tree generated by maximum likelihood analysis of combined ITS, *tefl*, and *act* sequence data of *Cladosporium* species

Figure 3.14 *Toxicocladosporium banksiae* (CBS 128215) was used as the outgroup. ML bootstrap support values $\geq 50\%$ (BT) and Bayesian posterior probabilities ≥ 0.90 (BYPP) are shown near the nodes. The scale bar indicates 0.007 changes per site. Isolates from the current study are in red, and type specimens are in bold.

3.2.3.3 Taxonomy

Cladosporium anthropophilum Sand.-Den., Gené & Wiederh., in Sandoval-Denis, Gené, Sutton, Wiederhold, Cano-Lira & Guarro, *Persoonia* 36: 290 (2016)

Asexual morph: Hyphomycetous. Mycelium superficial and immersed. Hyphae 2–4 μm wide, septate, unbranched or branched, subhyaline to pale olivaceous, smooth, thick-walled. Conidiophores up to 207 μm long, 2–4 μm wide, macro- and semi-macronematous, erect, cylindrical, sometimes geniculate, septate, branched or unbranched, pale olivaceous brown, non-nodulose, thick-walled. Conidia forming short branched chains with up to four conidia in the terminal unbranched part of the chain, small terminal conidia 4–7 \times 2–4 μm (\bar{x} = 5.4 \times 3.0 μm , n = 30), ovoid or ellipsoid; intercalary conidia 5–12 \times 2–4 μm (\bar{x} = 7.1 \times 2.9 μm , n = 30), limoniform to ellipsoidal, aseptate. Secondary ramoconidia 9–27 \times 2.5–3.5 μm (\bar{x} = 14.0 \times 3.0 μm , n = 30), ellipsoid to subcylindrical, often attenuated at the centre, 0–2-septate, smooth or finely roughened, subhyaline or pale olivaceous (Figure 3.15). **Sexual morph:** Not observed.

Culture characteristics – Colonies on PDA reaching 43–50 mm diam. after ten days at 25°C, entire margined, flat, velvety, aerial mycelium abundant, grey olivaceous to olivaceous, reverse leaden grey with white margin. Colonies on SNA reaching 34–40 mm diam. after ten days at 25°C, margin regular, flat, cottony, aerial mycelium loose diffuse, olivaceous, reverse olivaceous brown (Figure 3.15).

Material examined – China, Beijing, Tongzhou district, isolated from diseased leaves of *Prunus avium*, 11 July, 2019, Yueyan Zhou (JZBH390069–JZBH390072), living cultures JZB390069–JZB390072; *ibid.*, Fangshan district, isolated from diseased leaves of *Prunus avium*, September 22, 2021, Yueyan Zhou (JZBH390074), living cultures JZB390074; *ibid.*, Haidian district, isolated from diseased leaves of *Prunus avium*, September 27, 2022, Yueyan Zhou (JZBH390075), living cultures JZB390075.

Notes – Six new isolates (JZB390069–JZB390072, JZB390074–JZB390075) were clustered with the ex-type of *C. anthropophilum* (CBS 140685) with 84% ML bootstrap value and 1.0 BYPP. And the morphological characters of the isolates resembled the description of the ex-type (Sandoval-Denis et al., 2016). *Cladosporium anthropophilum* was first introduced in 2016 as a common saprobic fungus and then frequently isolated from clinical samples and indoor environments (Sandoval-Denis et al., 2016; Bensch et al., 2018). This is the first report of *C. anthropophilum* on sweet cherry.

Figure 3.15 *Cladosporium anthropophilum* (JZB390070)

Figure 3.15 A–B Culture on PDA from above (A) and reverse (B). C–D Culture on SNA from above (C) and reverse (D). E–G Conidiophores. H Conidial chains. (I) Conidia. Scale bars: E–I = 10 μm .

Cladosporium asperulatum Bensch, Crous & U. Braun, Stud. Mycol. 67: 21 (2010)

Asexual morph: Hyphomycetous. Mycelium immersed. Hyphae 2.5–4 μm wide, septate, unbranched, subhyaline to pale or medium olivaceous-brown, smooth to minutely verruculose or irregularly verruculose, walls not thickened or almost so, sometimes forming ropes. Conidiophores up to 182 μm long, 3–5 μm wide, macro- and micronematous, erect, cylindrical-oblong, sometimes slightly geniculate towards the apex, septate, unbranched, occasionally branched, pale to medium olivaceous-brown, non-nodulose, smooth to asperulate or minutely verruculose, walls slightly thickened. Conidia catenate, in branched chains, up to ten conidia in the terminal unbranched part of the chain; small terminal conidia 5–8.5 \times 2–4 μm (\bar{x} = 6.3 \times 3.1 μm , n = 30), ovoid; intercalary conidia 6–13 \times 2.5–4 μm (\bar{x} = 8.5 \times 3.3 μm , n = 30), ovoid, fusiform to ellipsoid, aseptate. Secondary ramoconidia 10–20 \times 3.5–5 μm (\bar{x} = 15.5 \times 3.9 μm , n = 30), ellipsoid, fusiform, subcylindrical, not constricted at septa, smooth to minutely

verruculose, subhyaline to pale olivaceous brown (Figure 3.16). **Sexual morph:** Not observed.

Culture characteristics – Colonies on PDA reaching 31–32 mm diam. after ten days at 25°C, entire margined, flat or folded, fluffy, aerial mycelium dense, grey olivaceous with white margin, reverse leaden-grey to iron-grey. Colonies on SNA reaching 24–25 mm diam. after ten days at 25°C, margin regular, flat, cottony, aerial mycelium abundant, pale-olivaceous, reverse olivaceous to olivaceous-brown (Figure 3.16).

Material examined – China, Beijing, Tongzhou district, isolated from diseased leaves of *Prunus avium*, 11 July, 2019, Yueyan Zhou (JZBH390076, JZBH390077), living cultures JZBH390076, JZBH390077; *ibid.*, Fangshan district, isolated from diseased leaves of *Prunus avium*, September 22, 2021, Yueyan Zhou (JZBH390078), living cultures JZB390078.

Notes – Three new isolates (JZBH390076–JZBH390078) were clustered with the ex-type of *C. asperulatum* (CBS 126340) with 89% ML bootstrap value and 1.0 BYPP. Morphologically, the isolates conformed to the description of the ex-type (Bensch et al., 2010). *Cladosporium asperulatum* was introduced in 2010 from plant materials (Bensch et al., 2010), while its effects on the plants have not been specifically reported. This is the first report of *C. asperulatum* on sweet cherry.

Figure 3.16 *Cladosporium asperulatum* (JZB390077)

Figure 3.16 A–B Culture on PDA from above (A) and reverse (B). C–D Culture on SNA from above (C) and reverse (D). E–G Conidiophores. H Conidial chains. I Conidia. Scale bars: E–I = 10 μm .

Cladosporium cladosporioides (Fresen.) G.A. de Vries, Contrib. Knowledge of the Genus *Cladosporium* Link ex Fries: 57 (1952)

Description — see Bensch et al. (2012).

Culture characteristics – Colonies on PDA reaching 47–50 mm diam. after ten days at 25°C, margin regular, flat to low convex, velvety to floccose, aerial mycelium dense, grey olivaceous, reverse leaden grey. Colonies on SNA reaching 32–33 mm diam. after ten days at 25°C, margin regular, flat, floccose, aerial mycelium loose to somewhat dense, light grey olivaceous, reverse olivaceous brown (Figure 3.17).

Material examined – China, Beijing, Tongzhou district, isolated from diseased leaves of *Prunus avium*, 11 July, 2019, Yueyan Zhou (JZBH390079, JZBH390080), living cultures JZB390079, JZB390080; *ibid.*, Fangshan district, isolated from diseased leaves of *Prunus avium*, 22 September, 2021, Yueyan Zhou (JZBH390081), living cultures

JZB390081; *ibid.*, Haidian district, isolated from diseased leaves of *Prunus avium*, 27 September, 2022, Yueyan Zhou (JZBH390082), living cultures JZB390082.

Notes – Four new isolates (JZBH390079–JZB390082) were clustered with the ex-type of *C. cladosporioides* (CBS 112388) with 92% ML bootstrap value and 1.0 BYPP. And their morphological characters conformed to the description of the ex-type (Bensch et al., 2012). *Cladosporium cladosporioides* is one of the most common saprophytic species, widely distributed in plants, air, soil, food and numerous other materials worldwide, and exists as an endophyte or secondary invader on faded or necrotic parts of many host plants (Bensch et al., 2012). The species was reported to cause leaf scab disease on papaya (Chen et al., 2009), blossom blight of red powder puff (Mukhtar et al., 2021), and fruit rot of grapes (Liu et al., 2021), and it was found to be the primary pathogens causing the core browning and moldy core of apples (Gao et al., 2013). In addition, it also has the potential to be a biocontrol agent. Köhl et al. (2015) found that the antagonistic strain of *C. cladosporioides* could reduce apple scab in leaves and fruits, which reached the same control levels as commercial fungicides. On cherry, *C. cladosporioides* was isolated from imported buds by Bensch et al. (2012).

Figure 3.17 *Cladosporium cladosporioides* (JZB390081)

Figure 3.17 A–B Culture on PDA from above (A) and reverse (B). C–D Culture on SNA from above (C) and reverse (D).

Cladosporium ramotenellum K. Schub., Zalar, Crous & U. Braun, in Schubert, Groenewald, Braun, Dijksterhuis, Starink, Hill, Zalar, de Hoog & Crous, Stud. Mycol. 58: 137 (2007)

Asexual morph: Hyphomycetous. Mycelium superficial. Hyphae 2–4.5 μm wide, septate, unbranched, hyaline or subhyaline, smooth, walls not thickened. Conidiophores up to 251 μm long, 2.5–5 μm wide, macro- and micronematous, erect, cylindrical, septate, usually unbranched, subhyaline to pale olivaceous or brown, non-nodulose, smooth to minutely verruculose, walls not thickened. Conidia numerous, forming short branched chains with up to six conidia in the terminal unbranched part of the chain; small terminal conidia 3–7 \times 2–4 μm (\bar{x} = 4.5 \times 3.0 μm , n = 30), globose, subglobose or ovoid, obovoid or limoniform, aseptate; intercalary conidia 6–12 \times 3–4 μm (\bar{x} = 8.6 \times 3.6 μm , n = 30), ellipsoid, limoniform to subcylindrical. Secondary ramoconidia 8–28 \times 2.5–5 μm , ellipsoid, subcylindrical to cylindrical-oblong, 0–3-septate, minutely verruculose, subhyaline to pale olivaceous (\bar{x} = 16.7 \times 3.8 μm , n = 30) (Figure 3.18). **Sexual morph:** Not observed.

Culture characteristics – Colonies on PDA reaching 40–57 mm diam. after ten days at 25°C, the margin slightly undulate, flat, powdery, olivaceous, reverse leaden grey. Colonies on SNA reaching 25–27 mm after ten days at 25°C, margin entire or slightly undulate, flat, aerial mycelium sparse, diffuse, olivaceous to olivaceous brown, reverse olivaceous brown (Figure 3.18).

Material examined – China, Beijing, Tongzhou district, isolated from diseased leaves of *Prunus avium*, 11 July 2019, Yueyan Zhou (JZBH390083–JZBH390085), living cultures JZB390083–JZB390085; *ibid.*, Tongzhou district, isolated from diseased leaves of *Prunus avium*, 20 October 2020, Yueyan Zhou (JZBH390086), living cultures JZB390086; *ibid.*, Fangshan district, isolated from diseased leaves of *Prunus avium*, 22 September 2021, Yueyan Zhou (JZBH390087), living cultures JZB390087.

Notes – Five new isolates (JZB390083–JZB390087) were clustered with the ex-type of *C. ramotenellum* (CBS 121628) with 86% ML bootstrap value and 1.0 BYPP. The isolates showed similar morphological characters to the original description of *C. ramotenellum* (Schubert et al., 2007). *Cladosporium ramotenellum* was initially isolated from indoor environments and water (Schubert et al., 2007). As a common

saprobic species, it has been reported to occur on various substrates with a wide geographic distribution (Bensch et al., 2015), and reported as a clinically relevant fungus in the United States (Sandoval-Denis et al., 2015). This is the first report of *C. ramotenellum* on sweet cherry.

Figure 3.18 *Cladosporium ramotenellum* (JZB390084)

Figure 3.18 A–B Culture on PDA from above (A) and reverse (B). C–D Culture on SNA from above (C) and reverse (D). (E, F) Conidiophores. (G) Conidial chains. (H) Conidia. Scale bars: E–H = 10 μ m.

Cladosporium rectoides Bensch, H.D. Shin, Crous & U. Braun, Stud. Mycol. 67: 73 (2010)

Description — see Bensch et al., (2012).

Culture characteristics – Colonies on PDA reaching 54–56 mm diam. after ten days at 25°C, margin regular, somewhat furrowed or wrinkled, velvety to floccose, aerial mycelium dense, olivaceous-grey to iron-grey, reverse leaden grey to olivaceous-black. Colonies on SNA reaching 31–35 mm diam. after ten days at 25°C, margin regular, flat, woolly-floccose, aerial mycelium loosely to densely floccose, olivaceous brown with a white margin, reverse brownish (Figure 3.19).

Material examined – China, Beijing City, Tongzhou district, isolated from diseased leaves of *Prunus avium*, 11 July 2019, Yueyan Zhou (JZBH390088, JZBH390089), living cultures JZB390088–JZB390089.

Notes – Two new isolates (JZBH390088 and JZBH390089) were clustered with the ex-type of *C. rectoides* (CBS 125994) with 99% ML bootstrap value and 1.0 BYPP. Morphologically, the isolates resembled the ex-type of *C. rectoides* (Bensch et al., 2010). *Cladosporium rectoides* was introduced from unknown plant materials, while the lifestyle was not provided (Bensch et al., 2010). This is the first report of *C. rectoides* on sweet cherry.

Figure 3.19 *Cladosporium rectoides* (JZB390089)

Figure 3.19 *Cladosporium rectoides* (JZB390089). A–B Culture on PDA from above (A) and reverse (B). C–D Culture on SNA from above (C) and reverse (D).

Cladosporium tenuissimum Cooke, Grevillea 6(no. 40): 140 (1878)

Asexual morph: Hyphomycetous. Mycelium immersed and superficial. Hyphae 2–4 μm wide, septate, branched, subhyaline to pale or medium brown, smooth to sometimes minutely verruculose, walls unthickened. Conidiophores up to 175 μm long, 2.5–4 μm wide, macronematous and micronematous, cylindrical-oblong to almost filiform, sometimes slightly to distinctly geniculate towards the apex, unbranched or branched, pale to medium brown or olivaceous-brown, non-nodulose or subnodulose, smooth, walls somewhat thickened. Conidia abundant, catenate, forming in densely branched chains with up to six conidia in the upper unbranched part; small terminal

conidia $3.5\text{--}6 \times 2\text{--}3 \mu\text{m}$ ($\bar{x} = 4.5 \times 2.5 \mu\text{m}$, $n = 30$), subglobose, obovoid, limoniform, sometimes globose, aseptate; intercalary conidia $4\text{--}14 \times 2\text{--}4 \mu\text{m}$ ($\bar{x} = 6.4 \times 2.9 \mu\text{m}$, $n = 30$), ovoid, ellipsoid or subcylindrical, aseptate. Secondary ramoconidia $13\text{--}22 \times 3.5\text{--}5 \mu\text{m}$ ($\bar{x} = 15.5 \times 4.0 \mu\text{m}$, $n = 30$), ellipsoid, fusiform to subcylindrical or cylindrical, 0-2 septate, smooth, pale brown or pale olivaceous-brown. **Sexual morph:** Not observed.

Culture characteristics – Colonies on PDA reaching 49–51 mm diam. after ten days at 25°C, margin regular, flat, powdery, grey olivaceous to dull green, reverse leaden grey to olivaceous black. Colonies on SNA reaching 26–30 mm after ten days at 25°C, margin regular, flat, floccose, aerial mycelium dense, olivaceous brown (Figure 3.20).

Material examined – China, Beijing City, Haidian district, isolated from diseased leaves of *Prunus avium*, 27 September 2022, Yueyan Zhou (JZBH390090), living cultures JZBH390090.

Notes – One new isolate (JZB390090) was clustered with the ex-type of *C. tenuissimum* (CBS 12995) with 82% ML bootstrap value and 1.0 BYPP. Morphologically, the isolate showed similar characteristics to *C. tenuissimum* (Bensch et al., 2010). This species is phenotypically similar to *C. cladosporioides* and often confused with the latter; thereby, the two species were divided based on the differences in genes and morphology, such as conidiophores, conidiogenous cells, conidial chains and secondary ramoconidia (Bensch et al., 2010; Bensch et al., 2012). *Cladosporium tenuissimum* is a common saprobe on numerous substrates and also a pathogen causing leaf spots on several hosts, including carnation (Xie et al., 2022), alfalfa (Han et al., 2019), and peanut (Geng et al., 2022). The species was also reported as one of the main pathogens causing the core browning and mouldy core of apples (Gao et al., 2013). This is the first report of *C. tenuissimum* on sweet cherry.

Figure 3.20 *Cladosporium tenuissimum* (JZB390090)

Figure 3.20 A–B Culture on PDA from above (A) and reverse (B). C–D Culture on SNA from above (C) and reverse (D). E Conidiophores. F–G Conidial chains. H Conidia. Scale bars: E–H = 10 μ m.

3.2.3.4 Summary

Cladosporium is a monophyletic genus in Cladosporiaceae with a wide ecological distribution and host range. It is one of the largest genera of dematiaceous hyphomycetes with a coronate structure, conidia in acropetal chains (David, 1997; Bensch et al., 2010). In this study, six *Cladosporium* species associated with cherry leaf spots were identified and characterized, among which *C. anthropophilum* is dominant (28.6%). Except for *C. cladosporioides* has been reported from cherry buds, *C. anthropophilum*, *C. asperulatum*, *C. ramotenellum*, *C. rectoides*, and *C. tenuissimum* are new host records on sweet cherry. Their pathogenicity on cherry needs to be further studied.

3.2.4 Two Additional Species from Cherry Leaf Spot

During fungal isolation of cherry leaf spot, except for the above main genera, one additional new host record species and one new species were identified.

Diaporthe beijingensis Y.Y. Zhou, W. Zhang & J.Y. Yan. *sp. nov.*

Index Fungorum number: IF902257; Facesoffungi number: FoF 15928 Figure 3.21

Etymology – ‘beijingensis’ refers to Beijing in China, from which it was isolated.

Associated with leaf spots of *Prunus avium* leaves. **Sexual morph:** Produced on 30 days old PDA culture. *Perithecia* 220–397 µm diam., subglobose, black, solitary to scattered, ostiolate. *Perithecial necks* 38–103 µm., black, subcylindrical, tapering towards the apex. *Asci* 25.6–37.2 × 5–8 µm (\bar{x} = 31.8 × 6.7 µm, n = 30), unitunicate, 8-spored, sessile, ellipsoid to clavate, widest at centre and rounded towards the apices. *Ascospores* 5.6–8.5 × 2–3 µm (\bar{x} = 6.5 × 2.6 µm, n = 50), hyaline, often biguttulate, ellipsoid to fusoid, **Asexual morph:** *Conidiomata* 180–350 µm diam., pycnidial, globose or irregular, scattered, orange cream conidial drops exuded from the ostioles. *Alpha conidia* 5–7.5 × 1.5–3 µm (\bar{x} = 6.9 × 2.7 µm, n = 60), hyaline, biguttulate, fusoid to ellipsoid, *Beta* and *Gamma* conidia not observed.

Culture characteristics – Colonies on PDA entirely white both on surface and reverse. Reverse become amber with time. Aerial mycelium felty, colonies reaching 75 mm diam. after 4 days in room temperature.

Material examined – China, Beijing, on leaf spot of *Prunus avium* L. (*Rosaceae*), 27 September 2022, Yueyan Zhou and Wei Zhang 22-HD-2-5a (JZBH320260, **holotype**), ex-type JZB320260.

Notes – *Diaporthe beijingensis* forms a distinct clade within *Diaporthe* and is sister to *D. caulivora* (Figure 3.22). It forms an independent branch with 100% ML support. The morphological characters of our new collection are similar to *D. caulivora* (CBS 127268, ex-neotype). However, base pair showed 2.1% (11/536) differences in ITS, 4.4% (15/343) in *tef*, 1.6% (7/429 bp) in *act*, 2.2% (8/356) in *cal*, and 3.2% (15/475) in *his* between *D. beijingensis* (JZB320260) and *D. caulivora* (CBS 127268). Therefore, we introduce *Diaporthe beijingensis* as a new species.

Figure 3.21 Morphological characters of *Diaporthe beijingsensis* (JZB320260, holotype)

Figure 3.21 a Surface, b Reverse view of 4-days old colony on PDA. c Ascomata. d Ascus. e Ascospores. f Conidiomata. g Conidia. Scale bars: c=20 μm; d, e=10 μm; f=100 μm; g=10 μm.

Figure 3.22 142 taxa were included in the combined analyses, which comprised 2151 characters in the alignment. Bootstrap support values equal or greater than for ML $\geq 60\%$ and BYPP ≥ 0.95 are given above the nodes. The tree is rooted with *Diaporthe sojae* (FAU635) and *D. actinidiae* (ICMP 13683). The ex-type strains are indicated in bold. The newly generated sequence is indicated in red.

Neopestalotiopsis rosae Maharachch., K.D. Hyde & Crous, in Maharachchikumbura, Hyde, Groenewald, Xu & Crous, Stud. Mycol. 79: 147 (2014)

Index Fungorum number: IF809777; Facesoffungi number: FoF03890; Figure 3.23

Associated with the leaf spot of *Prunus avium*. **Sexual morph:** Not observed. **Asexual morph:** *Conidiomata* globose, solitary, black, 200–500 μm diam. *Conidiophores* indistinct, often reduced to conidiogenous cells. *Conidiogenous cells* discrete, cylindrical, hyaline, 7–20 \times 3–5 μm . *Conidia* fusoid, ellipsoid, straight or slightly curved, 4-septate, 22–31 \times 5–9 μm (\bar{x} = 25.8 \times 7.3 μm , n = 50); basal cell conic to obconic with a truncate base, hyaline, 4–6 μm long; three median cells doliiform, brown, septa and periclinal walls darker than the rest of the cell, 16–18.5 μm long (second cell from base 4–6 μm long; third cell 4.5–6.5 μm long; fourth cell 4–7 μm long); apical cell 3–5 μm long, cylindrical, hyaline, with 2–4 tubular appendages, filiform, 21–35 μm long; basal appendage single, tubular, unbranched, centric, 4.5–10 μm long.

Material examined – China, Beijing, Fangshan District, on the leaf spot of *Prunus avium*, 22 September 2021, Yueyan Zhou, JZB340092.

Notes – The morphologies of the asexual morph of our fungal collection are similar to the holotype of *N. rosae* isolated from a stem lesion in *Rosa* sp. (Maharachchikumbura et al., 2014). According to the phylogenetic analyses, our collection (JZB340092) clustered with the ex-type strain of *N. rosae* (CBS 101057) with 77% ML and 0.91 BYPP bootstrap supports (Figure 3.24). The species has been reported on a wide range of hosts, including *Eucalyptus* spp. (Belisário et al., 2020; Santos et al., 2020), *Fragaria* \times *ananassa* (Essa et al., 2018; Rebollar-Alviter et al., 2020; Wu et al., 2020), *Paeonia suffruticosa* (Maharachchikumbura et al., 2014), *Persea americana* (Fiorenza et al., 2022), *Prunus avium* (this study), *Punica granatum* L. (Xavier et al., 2020), *Rosa* sp. (Maharachchikumbura et al., 2014), *Vaccinium corymbosum* (Rodríguez-Gálvez et al., 2020; Santos et al., 2022) and *Vitis vinifera* (Cosseboom & Hu, 2021; Zhou et al., 2023). The current study presents new host records of *N. rosae* on *Prunus avium* in China.

Figure 3.23 Morphological characters of *Neopestalotiopsis rosae* (JZB340092)

Figure 3.23 a the top view of a 5-day colony on PDA. b the bottom view of a 5-day colony on PDA. c Conidioma formed on PDA. d Conidiogenous cells. e–i Conidia. Scale bars: c = 100 μ m, d–i = 10 μ m.

Figure 3.24 Phylogram generated from the maximum likelihood analysis based on the combined ITS, *tub* and *tefl- α* sequence data of the genus *Neopestalotiopsis*

Figure 3.24 101 strains are included in the combined analyses. Tree topology of the maximum likelihood analysis is similar to the Bayesian analysis. The best RAxML tree with a final likelihood value of -5269.182443 is presented. The matrix had 386 distinct alignment patterns, with 4.32% of undetermined characters or gaps. Bootstrap

support values for ML greater than 60% and Bayesian posterior probabilities greater than 0.90 are given near nodes, respectively. The tree was rooted with *Pestalotiopsis colombiensis* (CBS 118553) and *Pestalotiopsis diversiseta* (MFLUCC 12-0287). Ex-type strains are in bold. The newly generated sequences are indicated in red.

3.2.5 A Summary of Fungal Species Associated with Cherry Leaf Spot Disease Around the World

The checklist is based on publications and a current study (Table 3.5). The current name is used according to Index Fungorum (2024) and the classification follows Hyde et al. (2024). Up to now, a total of forty-five species have been reported from cherry leaf spots.

Table 3.5 Records of fungal species associated with cherry leaf spot disease around the world

Species	Life mode	Disease name	Locality	Identification method	Reference
<i>Alternaria alternata</i>	Pathogen	Cherry leaf spot/ cherry black spot	China (BJ, GS, LN, QH); Greece	Morphology + multi-gene phylogeny	Thomidis and Tsipouridis (2006), Chethana et al. (2019), Liu et al. (2020), Yang et al. (2020), Zhao et al. (2013)
<i>Alternaria cerasi</i>	Pathogen	Cherry leaf spot	China (GS)	Morphology	Zhu & Chang (2004)

3.3 Discussion

Leaf spot is one of the most common and widespread diseases of sweet cherry. Though the disease was well-known to be caused by *Blumeriella jaapi* and *Pruniphilomyces circumscissus*, more findings of other species records are proving that the disease is caused by a mixed infection of various pathogens. As members of the top five groups of fungi associated with cherry leaf spot, *Colletotrichum*, *Fusarium* and *Cladosporium* species were identified in this study.

Colletotrichum is a well-known pathogen infecting a wide range of hosts, and there are emerging records of *Colletotrichum* species causing cherry leaf spot in recent years (Chethana et al., 2019; Tang et al., 2022; Zhou et al., 2023). Zhou et al. (2023) collected *Colletotrichum* isolates from different regions in China, among thirteen *Colletotrichum* species identified, *C. aenigma*, *C. gloeosporioides*, and *C. fructicola* accounted for the largest portion, suggesting that they could be dominant pathogens of anthracnose leaf spot. In this study, *Colletotrichum* isolates from Beijing were identified as the above species, which could add to the evidence of the importance of the three species. Zhou et al. (2023) found *C. aenigma* is ranked fourth in virulence on cherry leaves (cv. 'Tieton' and 'Summit') among thirteen species, following *C. conoides*, *C. dematium*, and *C. gloeosporioides*. However, *C. aenigma* inhibited low pathogenicity in this study, which only caused lesions on wounded leaves (cv. Caihong). The record of this species on sweet cherry was first reported by Chethana et al. (2019). In the pathogenicity test, it showed a significant difference in virulence on three cultivars, which reflected in producing much larger lesions on 'Summit' than 'Tieton' and 'Sunburst'. Also, the pathogenicity showed differences between isolates. This phenomenon could explain that the pathogenicity result is influenced by varieties and fungal strains.

Fusarium is one of the most renowned genera, which includes a large number of saprotrophs, endophytes or pathogens (Sandoval-Denis et al., 2018). As a common plant pathogen, *Fusarium* spp. can cause many diseases with a wide range of hosts, usually causing wilts, blights, rots, and cankers (Ma et al., 2013). *Fusarium* can also be the causal agent of leaf spot disease in several plants, including *Dracaena*, mango, peanut and *Bletilla striata* (Baka & Krzywinski, 1996; Guo et al., 2021; Xu et al., 2021;

Zhou et al., 2021). *Fusarium* species reported on sweet cherry are usually associated with trunk disease. *Fusarium oxysporum* has been reported as the pathogen of cherry root and crown rot in Canada (Úrbez-Torres et al., 2016), and *F. lateritium* was reported to cause trunk diseases in Australia (Cook & Dubé, 1989). Five *Fusarium* species have also been reported to cause postharvest rot on Chinese cherry (Wang et al., 2021). However, the occurrence of *Fusarium* on cherry leaf spot has not been reported before in the world. In this study, *Fusarium* species were identified as causal agents of cherry leaf spot for the first time. All seven species showed obvious pathogenicity on cherry leaves, and these species all have records as pathogens on other hosts (see 3.2.2.5 Summary); therefore, attention should be paid to *Fusarium* leaf spot on sweet cherry, which may cause severe damage in some conditions.

Cladosporium is a ubiquitous fungal genus distributed on a wide range of substrates, including plants, soil, food, clinical and other samples, as well as outdoor and indoor air (Bensch et al., 2012; Sandoval-Denis et al., 2016; Bensch et al., 2018). Members of *Cladosporium* exist on numerous plants as saprobes, endophytes and pathogens (Bensch et al., 2012). Leaf spots caused by *Cladosporium* species have been observed in many plants, including vegetables like spinach (du Toit et al., 2012), ornamental crops like carnation (Xie et al., 2022), and forage crops like alfalfa (Han et al., 2019). In addition, some of the species showed antagonistic potential against phytopathogens. For example, *C. cladosporioides* could reduce apple scab in leaves and fruits (Köhl et al., 2015), and *C. herbarum* has the biocontrol ability of *Eutypa dieback* of grapevine (Munkvold & Marois 1993). Though it is a widespread fungus, few reports of *Cladosporium* were on sweet cherry. Only *C. cladosporioides* and *C. phyllophilum* were reported to be isolated from imported buds of sweet cherry (Bensch et al., 2012). Six *Cladosporium* species were generated from cherry leaf spot in the current study. Several records of *C. cladosporioides* and *C. tenuissimum* on different hosts are associated with foliar, blossom and fruit diseases in China, while other species were usually reported as saprobes or environmental fungi. Their virulence on cherry leaves needs to be further studied to confirm that these *Cladosporium* species act as the main pathogens of this type of leaf spot, as secondary pathogens or only common saprobes.

The results also showed that different fungal genera were related to different symptoms. *Colletotrichum* is associated with circular to subcircular brown spots with dark-brown or purple margins, or brown leaf blights; *Fusarium* causes circular or irregular, purple-brownish to grey-brownish spots or necrotic lesions; and *Cladosporium* was isolated from leaf spots, including pinpoint lesions or irregular blights. However, the relationship between fungi and disease symptoms is still a preliminary speculation based on limited samples. In the field, it is usually difficult to distinguish the specific pathogen under the circumstances of mixed infection. Further research is necessary to understand the occurrence of pathogens in cherry diseases.

Different from the main fungal genera such as *Colletotrichum*, *Fusarium* and *Cladosporium*, some other fungi were occasionally found in cherry leaf spot. Two *Diaporthe* species have been reported to cause cherry leaf spot by Zhou et al. (2022), and a new species of *Diaporthe* was introduced in the current study. Additionally, *Neopestalotiopsis rosae*, which is a common pathogen on other hosts, was first reported in this study. Even though, there are only three isolates of *Diaporthe beijingensis* and one isolate of *Neopestalotiopsis rosae* were generated, they have not been related to the symptom types; Therefore, whether they are pathogenic on cherry leaves needs to be further studied.

This study also listed all the fungal species associated with cherry leaf spot, which provided a summary of the current research advances on fungal pathogens of the disease. Most pathogens previously identified only based on morphology or ITS sequence, phylogenetic analyses have been used in several recent papers, while some research still use the BLAST of single or several gene sequences for molecular identification. Compared with other important fruit crops, such as grape and strawberry, research on cherry disease is still limited.

In conclusion, the present study expands the knowledge, as well as provides a systematic review of fungal species associated with cherry leaf spot disease worldwide. These findings can serve as a valuable insight into the research on the occurrence regularity and management strategies of cherry leaf spot disease.

CHAPTER 4

IDENTIFICATION OF FUNGAL SPECIES ASSOCIATED WITH GRAPEVINE TRUNK DISEASE

4.1 Introduction

Among all woody agricultural plants, *Vitis vinifera* is known as the host that is affected by the widest variety of pathogens, especially fungal pathogens. According to statistics, *V. vinifera* is susceptible to 29 fungal diseases. Grapevine trunk diseases (GTDs) are among the most destructive diseases worldwide and have drawn considerable attention during the last few decades (Gramaje et al., 2018; Reis et al., 2019). They reduce vineyard longevity, productivity and quality, and the worldwide loss caused by the diseases is estimated to be \$1.5 billion annually (Hofstetter et al., 2012; Dissanayake et al., 2015a). Grapevine trunk diseases are a group of diseases causing necrosis and discoloration of wood and vascular tissue, even the death of the tree, including five types: Esca complex, Eutypa dieback, Botryosphaeria dieback, Black foot and Phomopsis (Diaporthe) dieback (Mondello et al., 2018; Ye et al., 2021a). Grapevine trunk diseases in fields are usually a mix of different disease types caused by various pathogens rather than a single one. Up to 2018, 133 fungal species belonging to 34 genera have been reported to be associated with grapevine trunk diseases (Gramaje et al., 2018). These fungi mainly act as latent pathogens, which can develop symptoms several years after the infection (Hrycan et al., 2020).

Esca disease complex is one of the oldest and most severe trunk diseases caused by *Phaeoconiella chlamydospora*, *Phaeoacremonium minimum* and a few other *Phaeoacremonium* spp. in all grapevine-growing areas worldwide. The history of the disease is possible as long as vine cultivation (Gramaje et al., 2018). Furthermore, some basidiomycete fungi like *Fomitiporia* species were also reported to cause Esca diseases (Clorte et al., 2015). In 2021, Ye and colleagues provided the first detailed report on the Esca complex in China, confirming that both *F. punicata* and *P. minimum* are the

causal agents of the Esca complex on Chinese grapevines (Ye et al., 2021b). This study also provided the first host record for *F. punicata* on the grapevine worldwide.

Botryosphaeria dieback is another important grapevine trunk disease reported in most grape-growing countries (Yan et al., 2013). More than 20 species from the Botryosphaeriaceae have been reported to cause Botryosphaeria dieback, including *Botryosphaeria* spp., *Diplodia* spp., *Dothiorella* spp., *Lasiodiplodia* spp., *Neofusicoccum* spp., *Neoscytalidium* spp., *Phaeobotryosphaeria* spp. and *Spencermartinsia* spp. (Gramaje et al., 2018). In China, Yan et al. (2013) first reported Botryosphaeria dieback in detail with its causative agents, *Botryosphaeria dothidea*, *Diplodia seriata*, *Lasiodiplodia theobromae*, and *Neofusicoccum parvum*. In addition, *Neofusicoccum mangiferae* and *Lasiodiplodia citricola* were also reported as pathogens of grapevine dieback in subsequent studies (Dissanayake et al., 2015b; Wu et al., 2021).

The black foot disease is a worldwide devastating grapevine trunk disease caused by *Cylindrocarpon*-like fungi, mainly in grapevine nurseries and young plantations and is commonly associated with species belonging to *Campylocarpon*, *Cylindrocladiella*, *Dactylonectria*, *Ilyonectria*, *Neonectria*, *Pleiocarpon* and *Thelonectria* (Gramaje et al., 2018; Lawrence et al., 2019). Ye et al. (2021c) first reported the black foot disease in China caused by five pathogens, *Cylindrocladiella lageniformis*, *Dactylonectria alcacerensis*, *D. macrodidyma*, *D. torresensis* and *Neonectria* sp. Recent studies have identified other fungi, such as *Campylocarpon fasciculare*, as causative agents of black foot disease on young grapevines in China (Abeywickrama et al., 2021). In addition, *Ilyonectria liriodendri* (former *Neonectria liriodendri*) has been reported as the pathogen of the black foot of grapevines in many countries (Jayawardena et al., 2018).

Furthermore, Diaporthe dieback is another disease categorised in the grapevine trunk disease complex worldwide. Currently, around 30 *Diaporthe* species have been identified as causal organisms of Diaporthe dieback in grape-producing countries, of which ten were reported in China (*D. eres*, *D. guangxiensis*, *D. hongkongensis*, *D. hubeiensis*, *D. gulyae*, *D. pescicola*, *D. phaseolorum*, *D. sojiae*, *D. unshiuensis*, *D. viniferae*), and *Diaporthe eres* proved to be the most commonly isolated species in both studies in 2015 and 2019 (Dissanayake et al., 2015a; Guarnaccia et al., 2018; Manawasinghe et al., 2019).

Eutypa dieback has been one of the most damaging diseases in Australia, France and California since the 1970s. To date, no effective measures are available to control this disease (Mondello et al., 2018). Among the 24 Diatrypaceae species that cause this disease, *Eutypa lata* is the most virulent and common (Gramaje et al., 2018). *Eutypa dieback* was first reported in China in 2007 with *Eutypella vitis* as the pathogen, but this has not been proved by Koch's postulates (Ye et al., 2021a).

Due to the complexity of the disease and the lack of the most effective chemical products, managing grapevine trunk diseases is difficult (Gramaje et al., 2018). It is well-accepted that grapevine trunk diseases should be managed by an integrated disease management strategy, including biological control (Gramaje et al., 2018).

4.2 Results

4.2.1 Field Sampling and Fungal Isolation

In 2021, grapevine trunk diseases were investigated in 14 grapevine orchards in Beijing, Fujian, Hebei, Hubei, Ningxia, Shaanxi, Shanxi and Yunnan Provinces, China (Figure 4.1).

Figure 4.1 Sample collection sites of grapevine trunk diseases in eight provinces in China

Figure 4.1 A–C leaf symptoms in the field. D–F leaf spot samples. Sample collection sites of grapevine trunk diseases in eight provinces in China. BJ: Beijing. FJ: Fujian. HB: Hubei. HE: Hebei. NX: Ningxia. SN: Shaanxi. SX: Shanxi. YN: Yunnan.

Diseased grapevines exhibited several symptoms (Figure 4.2):

1. Weak tree vigour: low growth, stunt sprout, small leaves and short internodes. Leaves discoloured or appear tiger-striped symptoms. Berries poorly developed or uneven ripening;

2. Dieback: usually evident in early spring, the tree cannot sprout normally, and branches are dried-up, even the whole plant wilting or dead. The trunk shows discoloured vascular tissues in a cross-section, sometimes appears canker lesions or black fruit bodies, and/or roots poorly developed;

3. Fruits shrivelled or dry rotted, stem brown and wilting, sometimes appears black fruit bodies on the surface.

The investigation results showed that plant decline, dieback, fruit shirking and fall-off are the major symptoms of grapevine trunk diseases in China, which lead to the reduction of productivity and life span of grapes. Grapevine trunk diseases were observed in nearly 20% of orchards, and the proportion of diseased plants was about 10% in the investigated fields, up to 100% in severe cases. Main grapevine trunk diseases including black foot, *Botryosphaeria* dieback and *Diaporthe* dieback were observed in this investigation.

4.2.2 Isolation Results of Grapevine Trunk Disease Samples

A total of 199 purified fungal isolates were obtained from 68 samples collected from eight provinces. Further, these isolates were identified into 40 species across 21 genera and ten families. Among them, 22 species were reported as new geographical records in China, and 12 were new host records (Table 4.1). *Diaporthe* was the most dominant (19.6%), followed by *Dactylonectria* (14.1%), *Fusarium* (10.6%), and *Botryosphaeria* (8.5%). Most Botryosphaeriaceae, Pestalotiopsis-like and Colletotrichum species were isolated from the trunk, while most *Dactylonectria* species were isolated from the root. *Diaporthe* and *Fusarium* were isolated from both trunk and root. *Dactylonectria*, *Botryosphaeria* and *Bartalinia* were widely distributed in China. Sequences generated in this study were deposited in the GenBank.

4.2.3 Phylogenetic Analysis and Morphological Characterization

Botryosphaeriaceae Theiss. & Syd [as ‘Botryosphaeriaceae’], *Annls mycol.* 16(1/2): 16 (1918)

The Botryosphaeriaceae comprises a wide range of species as pathogens, endophytes or saprobes mainly on woody hosts. They are also known as opportunistic pathogens with changing environmental conditions and weak tree vigour (Phillips et al., 2013; Chethana et al., 2016). Botryosphaeriaceae comprises 22 genera based on morphology and multi-gene phylogeny (Wijayawardene et al., 2021; Zhang et al., 2021), and eight genera have been reported to associate with grapevine trunk diseases (Gramaje et al., 2018).

In this study, thirty-seven isolates of Botryosphaeriaceae were obtained, belonging to *Botryosphaeria*, *Diplodia*, *Lasiodiplodia*, *Neofusicoccum* and *Phaeobotryon*, representing seven species. For taxonomic treatments of Botryosphaeriaceae, we follow Zhang et al. (2021).

Botryosphaeria Ces. & De Not., *Comm. Soc. crittog. Ital.* 1 (fasc. 4): 211 (1863)

Botryosphaeria dothidea (Moug.: Fr.) Ces. & De Not., *Comm. Soc. crittog. Ital.* 1 (fasc. 4): 212 (1863)

Index Fungorum number: IF183247; Facesoffungi number: FoF 03512

Description – see Phillips et al., (2013)

Material examined – China, Hubei Province, Wuhan City, on the trunk of *Vitis vinifera*, 28 April 2021, Linna Wu and Xinghong Li, living cultures JZB310204, JZB310205; *ibid.*, Yunnan Province, Binchuan County, on the trunk of *Vitis vinifera*, 23 July 2021, Linna Wu and Xinghong Li, living cultures JZB310206, JZB310211–JZB310214; *ibid.*, on the root of *Vitis vinifera*, 23 July 2021, Linna Wu and Xinghong Li, living cultures JZB310207; *ibid.*, Beijing city, on the trunk of *Vitis vinifera*, 25 August 2021, Linna Wu and Xinghong Li, living cultures JZB310208–JZB310210; *ibid.*, 11 September 2021, Linna Wu and Xinghong Li, living cultures JZB310215, JZB310216; *ibid.*, Hebei Province, Qinhuangdao City, Changli County, on the trunk of *Vitis vinifera*, 18 October 2021, Linna Wu and Xinghong Li, living cultures JZB310217, JZB310218; *ibid.*, on the trunk-base of *Vitis vinifera*, 13 November 2021, Linna Wu and Xinghong Li, living cultures JZB310219, JZB310220.

Notes – In the multi-locus phylogenetic analyses, 17 isolates clustered with *B. dothidea* with 69% ML bootstrap value and 0.95 BYPP (Figure 4.3). *Botryosphaeria dothidea* is an opportunistic pathogen with a wide host range (Marsberg et al., 2017). Yan et al. (2013) have mentioned that *B. dothidea* was distributed in 18 provinces from north to south throughout China and took up 65% of all isolates among *Botryosphaeria* dieback pathogens in China (Yan et al., 2013).

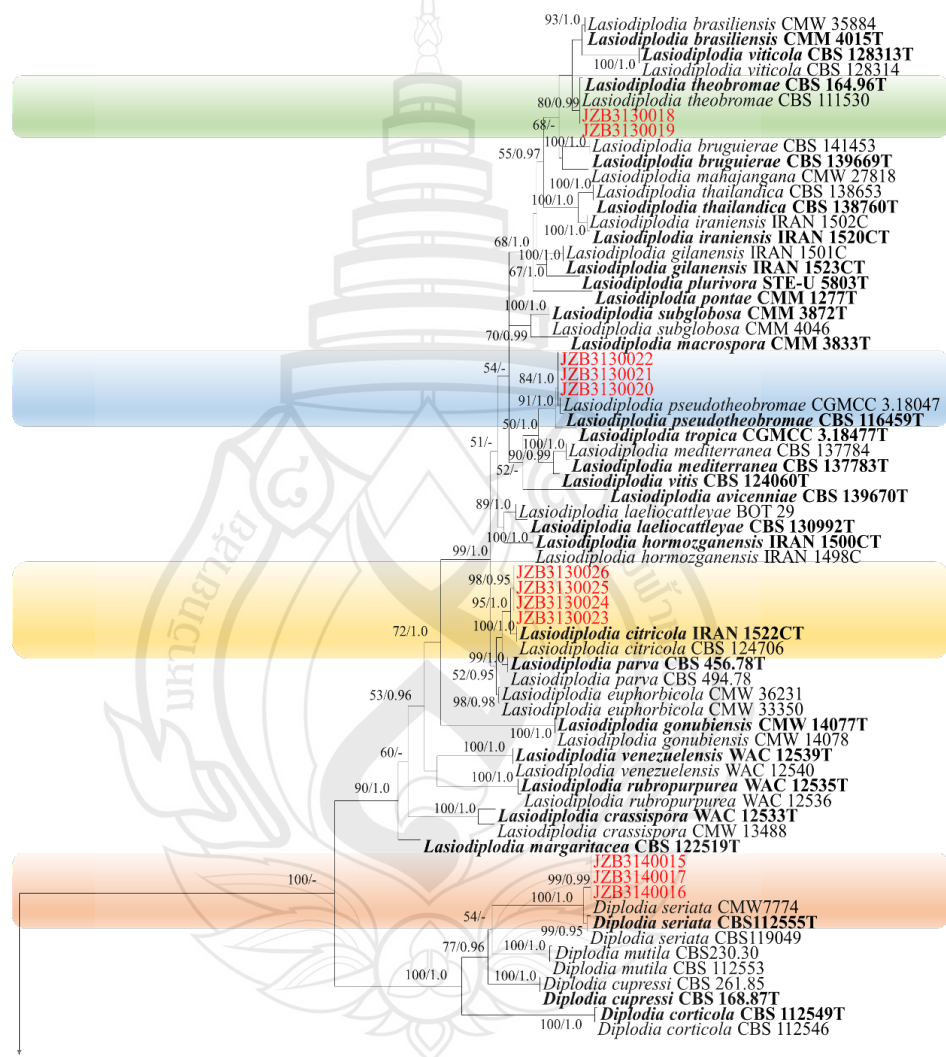

Figure 4.3 Phylogenetic tree generated by maximum likelihood analysis of combined ITS, *tef1* and *tub2* sequence data of *Botryosphaeria*, *Lasiodiplodia*, *Neofusicoccum* and *Diplodia* species

Figure 4.3 (Continued)

Figure 4.3 *Phyllosticta citricarpa* (CBS 127454) was used as the outgroup taxon. The best scoring RAXML tree with a final likelihood value of -8506.960370 was presented. The matrix had 695 distinct alignment patterns, with 19.31% of undetermined characters or gaps. Estimated base frequencies were as follows: A = 0.209952, C = 0.307342, G = 0.257379, T = 0.225327; substitution rates AC = 0.761022, AG = 2.876149, AT = 1.271062, CG = 1.067796, CT = 4.612694, GT = 1.000000; gamma distribution shape parameter $\alpha = 0.659641$. ML bootstrap support values $\geq 50\%$ (BT) and Bayesian posterior probabilities ≥ 0.90 (PP) are shown near the nodes. The scale bar indicates 0.08 changes per site. Isolates from the current study are in red and type specimens are in bold.

Description – see Phillips et al. (2013)

Material examined – China, Hebei Province, Zhangjiakou City, Huailai County, on the trunk of *Vitis vinifera*, 22 August 2020, Linna Wu and Xinghong Li, living cultures JZB3140015–JZB3140017.

Notes – In the multi-locus phylogenetic analysis, three isolates clustered with *D. seriata* with 100% bootstrap value and 1.0 BYPP (Figure 4.3). The species were shown to be weakly pathogenic to grapevines in California (Úrbez-Torres & Gubler, 2009). In China, *D. seriata* was first reported by Yan et al. (2011b) on grapevine and its pathogenicity was also shown moderate virulence on most grapevine cultivars in China (Yan et al., 2013).

Lasiodiplodia Ellis & Everh., Bot. Gaz. 21: 92 (1896)

Lasiodiplodia citricola Abdollahz., Javadi & A.J.L. Phillips, Persoonia 25: 4 (2010)

Index Fungorum number: IF516777; Facesoffungi number: FoF 09503

Description – see Phillips et al. (2013)

Material examined – China, Hebei Province, Qinhuangdao City, Changli County, on the trunk base of *Vitis vinifera*, 13 November 2021, Linna Wu and Xinghong Li, living cultures JZB3130023–JZB3130026.

Notes – In the multi-locus phylogenetic analysis, four isolates clustered with *L. citricola* with 95% ML bootstrap value and 1.0 BYPP (Figure 4.3). *Lasiodiplodia citricola* was first reported on the grapevine in Italy in 2015 and showed aggressive pathogenicity (Carlucci et al., 2015). In 2020, it was first reported in China (Wu et al., 2021), causing severe symptoms or death of grapevine.

Lasiodiplodia pseudotheobromae A.J.L. Phillips, A. Alves & Crous, Fungal Diversity 28: 8 (2008)

Index Fungorum number: IF510941; Facesoffungi number: FoF 00166

Description – see Phillips et al. (2013)

Material examined – China, Yunnan Province, Binchuan County, on the trunk of *Vitis vinifera*, 23 July 2021, Linna Wu and Xinghong Li, living cultures JZB3130020; *ibid.*, on the root of *Vitis vinifera*, 23 July 2021, Linna Wu and Xinghong Li, living cultures JZB3130021, JZB3130022.

Notes – In the multi-locus phylogenetic analysis, three isolates clustered with *L. pseudotheobromae* with 84% ML bootstrap value and 1.0 BYPP (Figure 4.3). *Lasiodiplodia pseudotheobromae* was first reported to cause the grapevine decline in Brazil (Correia et al., 2013) and was reported to cause pedicel and peduncle discolouration of grapes in China (Dissanayake et al., 2015c).

Lasiodiplodia theobromae (Pat.) Griffon & Maubl., Bull. Soc. mycol. Fr. 25: 57 (1909)

Index Fungorum number: IF188476; Facesoffungi number: FoF 00167

Description – see Phillips et al. (2013)

Material examined – China, Hubei Province, Wuhan City, on the trunk of *Vitis vinifera*, 13 November 2021, Linna Wu and Xinghong Li, living cultures JZB3130018, JZB3130019.

Notes – In the multi-locus phylogenetic analyses, two isolates clustered with *L. theobromae* with 80% ML bootstrap value and 0.99 BYPP (Figure 4.3). *Lasiodiplodia theobromae* is one of the most aggressive causal agents of Botryosphaeria dieback, especially in regions with hot climates (Úrbez-Torres & Gubler, 2009; Paolinelli-Alfonso et al., 2016). In 2011, this species was first reported to cause severe grapevine decline in China and was shown to be the most virulent among Botryosphaeriaceae species on grapevines (Yan et al., 2011a, 2013).

Neofusicoccum Crous, Slippers & A.J.L. Phillips, Stud. Mycol. 55: 247 (2006)

Neofusicoccum parvum (Pennycook & Samuels) Crous, Slippers & A.J.L. Phillips, in Crous, Slippers, Wingfield, Rheeder, Marasas, Phillips, Alves, Burgess, Barber & Groenewald, Stud. Mycol. 55: 248 (2006)

Index Fungorum number: IF500879; Facesoffungi number: FoF 02411

Description – see Phillips et al. (2013)

Material examined – China, Yunnan Province, Binchuan County, on the root of *Vitis vinifera*, 23 July 2021, Linna Wu and Xinghong Li, living cultures JZB3120008; *ibid.*, on the trunk of *Vitis vinifera*, 23 July 2021, Linna Wu and Xinghong Li, living cultures JZB3120009.

Notes – In the multi-locus phylogenetic analysis, two isolates clustered with *N. parvum* with 75% bootstrap value and 1.0 BYPP (Figure 4.3). *Neofusicoccum parvum* is one of the most aggressive Botryosphaeria dieback pathogens worldwide. This species can cause internal cankers in the permanent woody structure of the vine (Úrbez-Torres & Gubler, 2009; Massonnet et al., 2017). In China, *N. parvum* was first reported as a grapevine Botryosphaeria dieback pathogen in 2013 while it showed weak pathogenicity on grapevines (Yan et al., 2013).

Phaeobotryon Theiss. & Syd., Anns mycol. 13(5/6): 664 (1915)

Phaeobotryon rhois C.M. Tian, X.L. Fan & K.D. Hyde, in Fan, Hyde, Liu, Liang & Tian, Phytotaxa 205(2): 95 (2015)

Index Fungorum number: IF 811599; Facesoffungi number: FoF 00596

Asexual morph: *Conidiomata* stromatic, globose. *Conidiophores* reduced to conidiogenous cells. *Conidiogenous cells* hyaline, smooth, formed from the cells lining the inner walls of the locules. *Conidia* 19–28 × 11–15 µm, ($\bar{x} \pm SD = 23.5 \pm 1.8 \times 12.5 \pm 1.0$ µm, n = 50), ellipsoid or ovoid, verruculose, initially hyaline, aseptate, and become brown with the time, 1-septate when mature (Figure 4.4). Sexual morph: Not observed.

Culture characteristics – Colonies on PDA were initially white with fluffy aerial mycelium, and later produced dark green to black pigments (Figure 4.4). Colonies reached 8.0 cm in diameter after 2 days at 25°C.

Material examined – China, Ningxia Province, Yinchuan City, on the trunk of *Vitis vinifera*, 15 September 2021, Linna Wu and Xinghong Li (Inactive dry cultures JZBH3600001–JZBH3600003), living cultures JZB3600001–JZB3600003; *ibid.*, on the root of *Vitis vinifera*, 15 September 2021, Linna Wu and Xinghong Li (Inactive dry cultures JZBH3600004–JZBH3600006), living cultures JZB3600004–JZB3600006.

Notes – In the multi-locus phylogenetic analysis, six isolates clustered with *P. rhois* with 99% bootstrap value and 1.0 BYPP (Figure 4.5). This species was reported to cause dieback and canker disease on *Rhus typhina* in China (Fan et al., 2015), as well

as *Dioscorea nipponica*, *Platycladus orientalis* and *Rhamnus dahuricus* in China (Pan et al., 2019). This is the first report of *P. rhois* associated with grapevine trunk diseases in China.

Figure 4.4 Morphological characterization of *Phaeobotryon rhois* (JZB3600005)

Figure 4.4 a Upper view of the colony on PDA. b Reverse view of the colony on PDA. c A cross section of a conidioma. d–f Conidiophores and conidiogenous cells. g–j Mature and immature conidia. Scale bars: c = 100 μm , d–f, h–j = 10 μm , g = 20 μm .

Figure 4.5 Phylogenetic tree generated by maximum likelihood analysis of combined ITS, *tef1* and LSU sequence data of *Phaeobotryon* species

Figure 4.5 *Barriopsis fusca* (CBS 174.26) was used as the outgroup taxon. The best-scoring RAxML tree with a final likelihood value of -3653.517425 was presented. The matrix had 185 distinct alignment patterns, with 23.97% of undetermined characters or gaps. Estimated base frequencies were as follows: A = 0.230084, C = 0.261877, G = 0.279321, T = 0.228718; substitution rates AC = 1.390053, AG = 2.937002, AT = 0.769951, CG = 0.806736, CT = 7.065592, GT = 1.000000; gamma distribution shape parameter α = 0.839033. ML bootstrap support values $\geq 50\%$ (BT) and Bayesian posterior probabilities ≥ 0.90 (BYPP) are shown near the nodes. The scale bar indicates 0.007 changes per site. Isolates from the current study are in red and type specimens are in bold.

Nectriaceae Tul. & C. Tul. [as ‘Nectriei’], *Select. fung. carpol.* (Paris) 3: 3 (1865)

***Cylindrocarpon*-like fungi**

Cylindrocarpon-like species are widely distributed, soil-borne fungi around the world, including *Campylocarpon*, *Cylindrocladiella*, *Cylindrodendrum*, *Dactylonectria*, *Ilyonectria*, *Neonectria*, *Pleiocarpon* and *Thelonectria* (Capote et al., 2022). This group is considered as saprophytic or pathogenic causing cankers, root rot and decay of grapevines and many other plants (Jankowiak et al., 2016; Capote et al., 2022). Among them, all genera except *Cylindrodendrum* have been reported on the grapevines (Ye et al., 2021a). In this study, thirty-nine isolates representing six species belonging to *Dactylonectria*, *Ilyonectria* and *Cylindrocladiella* were identified. For taxonomic treatments, we follow Lu et al. (2020) and Ye et al. (2021a).

Dactylonectria novozelandica L. Lombard & Crous, in Lombard, van der Merwe, Groenewald & Crous, *Phytopath. Mediterr.* 53(3): 523 (2014)

Index Fungorum number: IF810150; Facesoffungi number: FoF 14330

Description – see Lombard et al., (2014)

Material Examined – China, Yunnan Province, Binchuan County, on the root of *Vitis vinifera*, 23 July 2021, Linna Wu and Xinghong Li, living cultures JZB3310031–JZB3310034; China, Hebei Province, Qinhuangdao City, Changli County, on the trunk-base of *Vitis vinifera*, 13 November 2021, Linna Wu and Xinghong Li, living cultures JZB3310035, JZB3310036; *ibid.*, on the root of *Vitis vinifera*, 13 November 2021, Linna Wu and Xinghong Li, living cultures JZB3310037, JZB3310038; China, Beijing City, on the root of *Vitis vinifera*, 11 September 2021, Linna Wu and Xinghong Li, living cultures JZB3310039–JZB3310042.

Notes – In the multi-locus phylogenetic analysis, twelve isolates clustered with *D. novozelandica* with 96% bootstrap value and 0.95 BYPP (Figure 4.6). *Dactylonectria novozelandica* has been reported to cause black foot disease from grapevines in China (Tan et al., 2022).

Dactylonectria alcacerensis (A. Cabral, H. Oliveira & Crous) L. Lombard & Crous, in Lombard, van der Merwe, Groenewald & Crous, *Phytopath. Mediterr.* 53(3): 525 (2014)

Index Fungorum number: IF810143; Facesoffungi number: FoF 14331

Description – see Cabral et al. (2012)

Material Examined – China, Shanxi Province, Linfen City, on the root of *Vitis vinifera*, 23 June 2021, Linna Wu and Xinghong Li, living cultures JZB3310021–JZB3310024; China, Beijing City, on the root of *Vitis vinifera*, 11 September 2021, Linna Wu and Xinghong Li, living cultures JZB3310025, JZB3310026; *ibid.*, 27 April 2021, Haiyun Hai and Xinghong Li, living cultures JZB3310029, JZB3310030; China, Hebei Province, Qinhuangdao City, Changli County, on the root of *Vitis vinifera*, 18 October 2021, Linna Wu and Xinghong Li, living cultures JZB3310027, JZB3310028.

Notes – In the multi-locus phylogenetic analysis, ten isolates clustered with *D. alcacerensis* with 99% bootstrap value and 1.0 BYPP (Figure 4.6). *Dactylonectria alcacerensis* has been reported as a pathogen causing the black foot disease of grapevines in China (Ye et al., 2021a).

Dactylonectria torresensis (A. Cabral, Rego & Crous) L. Lombard & Crous, in Lombard, van der Merwe, Groenewald & Crous, *Phytopath. Mediterr.* 53(3): 528 (2014)

Index Fungorum number: IF810153; Facesoffungi number: FoF 14332

Description – see Lombard et al. (2014)

Material Examined – China, Hebei Province, Huailai County, on the root of *Vitis vinifera*, 9 July 2021, Linna Wu and Xinghong Li, living cultures JZB3310046, JZB3310047; China, Ningxia Province, Yinchuan City, on the root of *Vitis vinifera*, 15 September 2021, Linna Wu and Xinghong Li, living cultures JZB3310048.

Notes – In the multi-locus phylogenetic analysis, three isolates clustered with *D. torresensis* with 99% bootstrap value and 1.0 BYPP (Figure 4.6). *Dactylonectria torresensis* has been reported to cause the black foot disease of grapevines in China (Ye et al., 2021a).

Dactylonectria macrodidyma (Halleen, Schroers & Crous) L. Lombard & Crous, in Lombard, van der Merwe, Groenewald & Crous, *Phytopath. Mediterr.* 53(3): 527 (2014)

Index Fungorum number: IF810147; Facesoffungi number: FoF 14333

Description – see Halleen et al. (2004)

Material Examined – China, Yunnan Province, Binchuan County, on the trunk of *Vitis vinifera*, 23 July 2021, Linna Wu and Xinghong Li, living cultures JZB3310043, JZB3310044; China, Beijing City, on the transition region between trunk and root of *Vitis vinifera*, 27 April 2021, Haiyun Tan and Xinghong Li, living cultures JZB3310045.

Notes – In the multi-locus phylogenetic analysis, three isolates clustered with *D. macrodidyma* with 100% bootstrap value and 1.0 BYPP (Figure 4.6). *Dactylonectria macrodidyma* is one of the causal agents of the black foot disease of grapevine in China and was verified to be the most aggressive on detached green shoots among five species associated with black foot disease of grapevine (*C. lageniformis*, *D. alcacerensis*, *D. macrodidyma*, *D. torresensis* and *Neonectria* sp. 1) (Ye et al., 2021a).

Ilyonectria P. Chaverri & Salgado, in Chaverri, Salgado, Hirooka, Rossman & Samuels, Stud. Mycol. 68: 69 (2011)

Ilyonectria liriodendri (Halleen, Rego & Crous) P. Chaverri & Salgado, in Chaverri, Salgado, Hirooka, Rossman & Samuels, Stud. Mycol. 68: 71 (2011)

Index Fungorum number: IF518561; Facesoffungi number: FoF 14355

Asexual morph: *Macroconidia* predominating, 1–3-septate, straight to slightly curved, cylindrical, 3-septate macroconidia 24–40 × 4–7 µm ($\bar{x} \pm SD = 29.0 \pm 3.7 \times 5.1 \pm 0.5$ µm, n = 50). *Microconidia* ellipsoidal, subcylindrical to ovoid, 0–1-septate, 6–14 × 3–4 µm, ($\bar{x} \pm SD = 9.2 \pm 1.7 \times 3.5 \pm 0.4$ µm, n = 50) (Figure 4.7). Sexual morph: Not observed.

Culture characteristics – Colonies on PDA white with sparse aerial mycelium, reverse pale orange (Figure 4.7), colonies reached 4.5 cm diam after 6 d.

Material Examined – China, Shanxi Province, Linfen City, on the root of *Vitis vinifera*, 23 June 2021, Linna Wu and Xinghong Li (Inactive dry cultures JZBH3610001, JZBH3610002), living cultures JZB3610001, JZB3610002; China, Ningxia Province, Yinchuan City, on the trunk of *Vitis vinifera*, 15 September 2021, Linna Wu and Xinghong Li (Inactive dry cultures JZBH3610003–JZBH3610006), living cultures JZB3610003–JZB3610006; China, Beijing City, on the transition region between trunk and root of *Vitis vinifera*, 27 April 2021, Haiyun Tan and Xinghong Li (Inactive dry cultures JZBH3610007), living cultures JZB3610007.

Notes – In the multi-locus phylogenetic analysis, seven isolates clustered with *I. liriodendri* with 98% ML bootstrap value and 1.0 BYPP (Figure 4.8). *Ilyonectria liriodendri* (former *Neonectria liriodendri*) has been reported as the pathogen of black foot of grapevines in many countries (Jayawardena et al., 2018). This is the first report of *I. liriodendri* on grapevines in China.

Figure 4.10 *Gliocladiopsis sagariensis* (CBS 199.55) was used as the outgroup taxon. The best scoring RAxML tree with a final likelihood value of -7461.214703 was presented. The matrix had 539 distinct alignment patterns, with 14.16% of undetermined characters or gaps. Estimated base frequencies were as follows: A = 0.224070, C = 0.307547, G = 0.220194, T = 0.248188; substitution rates AC = 1.015860, AG = 3.279433, AT = 0.995371, CG = 0.438164, CT = 4.326124, GT = 1.000000; gamma distribution shape parameter α = 0.505492. ML bootstrap support values $\geq 50\%$ (BT) and Bayesian posterior probabilities ≥ 0.90 (BYPP) are shown near the nodes. The scale bar indicates 0.05 changes per site. Isolates from the current study are in red and type specimens are in bold.

***Fusarium* and allied fusarioid genera**

Fusarium includes a large number of species as saprobes, endophytes or pathogens (Sandoval-Denis et al., 2018). Among them, *F. graminearum* and *F. oxysporum* are ranked as the top 10 fungal pathogens with scientific and economic importance (Dean et al., 2012). *Neocosmospora*, previously known as *F. solani* species complex (FFSC), includes the most important and ubiquitous groups of pathogens (Sandoval-Denis et al., 2019). *Bisifusarium* is a new genus proposed in recent years, encompasses species previously included in the *Fusarium dimerum* species complex (Sandoval-Denis et al., 2018).

In this study, thirty-four isolates from seven species belonging to *Fusarium*, *Neocosmospora* and *Bisifusarium* were identified (Figure 4.11). For taxonomic treatments, we followed Crous et al. (2021).

Figure 4.11 (Continued)

Figure 4.11 *Fusicolla aquaeductuum* (CBS 734.79) was used as the outgroup taxon. The best-scoring RAxML tree with a final likelihood value of -18302.824510 was presented. The matrix had 945 distinct alignment patterns, with 15.67% of undetermined characters or gaps. Estimated base frequencies were as follows: A = 0.251509, C = 0.269104, G = 0.244341, T = 0.235046; substitution rates AC = 1.483783, AG = 4.460272, AT = 1.757600, CG = 0.850730, CT = 9.879030, GT = 1.000000; gamma distribution shape parameter $\alpha = 1.224492$. ML bootstrap support values $\geq 50\%$ (BT) and Bayesian posterior probabilities ≥ 0.90 (BYPP) are shown near the nodes. The scale bar indicates 0.09 changes per site. Isolates from the current study are in red and type specimens are in bold.

Fusarium acuminatum Ellis & Everh., Proc. Acad. nat. Sci. Philad. 47: 441 (1895)

Index Fungorum: IF219366; Facesoffungi number: FoF 14334

Description – See Leslie and Summerell (2006)

Material Examined – China, Ningxia Province, Yinchuan City, on the trunk of *Vitis vinifera*, 15 September 2021, Wei Zhang and Xinghong Li, living cultures JZB3110195, JZB3110196; China, Shanxi Province, Linfen City, on the trunk of *Vitis vinifera*, 23 June 2021, Linna Wu and Xinghong Li, living cultures JZB3110197, JZB3110198.

Notes – In the multi-locus phylogenetic analysis, four isolates clustered with *F. acuminatum* with 98% bootstrap value and 1.0 BYPP (Figure 4.11). *Fusarium acuminatum* has been reported as a pathogen of grapevine wilt in Spain (Jayawardena et al., 2018). This is the first report of *F. acuminatum* associated with grapevine trunk diseases in China.

Fusarium brachygibbosum Padwick, Mycol. Pap. 12: 11 (1945)

Index Fungorum: IF286508; Facesoffungi number: FoF 11683

Asexual morph: *Macroconidia* formed in orange sporodochia on the carnation leaf agar (CLA), slightly curved, with wide central cells, slightly sharp apical cell and distinct foot basal cells, usually have 5 septa, $23\text{--}59 \times 5\text{--}6 \mu\text{m}$ ($\bar{x} \pm \text{SD} = 44.8 \pm 5.9 \times 5.7 \pm 0.4 \mu\text{m}$, $n = 50$). *Spherical chlamydospores* were produced from mycelium (Figure 4.12). Sexual morph: Not observed.

Culture characteristics – Colonies on PDA were initially white with abundant aerial mycelium, turning light orange in the centre, reverse orange (Figure 4.12). Colonies reached 7.7 cm in diameter after 4 days at 25°C.

Material Examined – China, Beijing City, on the root of *Vitis vinifera*, 11 September 2021, Linna Wu and Xinghong Li (Inactive dry cultures JZBH3110191–JZBH3110194), living cultures JZB3110191–JZB3110194.

Notes – In the multi-locus phylogenetic analysis, four isolates clustered with *F. brachygibbosum* with 100% bootstrap value and 1.0 BYPP (Figure 4.11). *Fusarium brachygibbosum* was reported to cause root rot of soybean, tobacco and maize stalk rot in China (Shan et al., 2017; Wang et al., 2021; Qiu et al., 2021). This is the first report of *F. brachygibbosum* associated with grapevine trunk diseases in China.

Fusarium compactum (Wollenw.) Raillo, *Fungi of the Genus Fusarium*: 180 (1950)

Index Fungorum: IF297537; Facesoffungi number: FoF 14337

Asexual morph: Orange *sporodochia* formed on the CLA. *Macroconidia* produced from monophialides on branched conidiophores in sporodochia, have strong dorsi-ventral curvature with a pronounced foot cell and tapering elongate apical cell that is often needle like in appearance, usually 5-septate, $41\text{--}91 \times 3\text{--}7 \mu\text{m}$ ($\bar{x} \pm \text{SD} = 66.7 \pm 11.8 \times 5.0 \pm 0.6 \mu\text{m}$, $n = 50$) (Figure 4.13). Sexual morph: Not observed.

Culture characteristics – Colonies on PDA were white with cottony, dense mycelium, and then turned light orange in centre, reverse orange (Figure 4.13). Colonies reached 6.9 cm in diameter after 4 days at 25°C.

Material Examined – China, Yunnan Province, Binchuan County, on the trunk of *Vitis vinifera*, 23 July 2021, Linna Wu and Xinghong Li (Inactive dry cultures JZBH3110190), living cultures JZB3110190.

Notes – In the multi-locus phylogenetic analysis, one isolate clustered with *F. compactum* with 100% bootstrap value and 1.0 BYPP (Figure 4.11). *Fusarium compactum* was reported to cause wheat root and crown rot in Turkey (Tunali et al., 2008), or saprotroph on apples in Croatia (Sever et al., 2012). This is the first report of *F. compactum* associated with grapevine trunk diseases in the world.

Figure 4.13 Morphological characterization of *Fusarium compactum* (JZB3110190)

Figure 4.13 a Upper view of the colony on PDA. b Reverse view of the colony on PDA. c Sporodochia formed on the surface of carnation leaves. d Conidiophores. e, f Macroconidia. Scale bars: c = 50 μ m, d–f = 10 μ m.

Fusarium hainanense M.M. Wang, Qian Chen & L. Cai, in Wang, Chen, Diao, Duan & Cai, *Persoonia* 43: 82 (2019)

Index Fungorum: IF829536; Facesoffungi number: FoF 14335

Asexual morph: *Sporodochia* light orange on CLA. *Conidiophores* unbranched. *Macroconidia* fusiform to falcate, straight to slightly curved, sometimes with constricted septa, have barely- to distinctly- notched basal cell and blunt to papillate apical cell, 1–5-septate, $17\text{--}39 \times 3\text{--}5 \mu\text{m}$, ($\bar{x} \pm \text{SD} = 27.6 \pm 6.8 \times 4.1 \pm 0.5 \mu\text{m}$, $n = 50$) (Figure 4.14). Sexual morph: Not observed.

Culture characteristics – Colonies on PDA were white with scant aerial mycelia, reverse pale orange in the centre, white at the margin. Colonies reached 8.1 cm diam after 4 days at 25°C (Figure 4.14).

Material Examined – China, Yunnan Province, Binchuan County, on the trunk of *Vitis vinifera*, 23 July 2021, Linna Wu and Xinghong Li (Inactive dry cultures JZBH3110199, JZBH3110200), living cultures JZB3110199, JZB3110200.

Notes – In the multi-locus phylogenetic analysis, two isolates clustered with *F. hainanense* with 100% bootstrap value and 1.0 BYPP (Figure 4.11). *Fusarium hainanense* was first isolated from rice as an endophyte in China (Wang et al., 2019). This is the first host report of *F. hainanense* associated with grapevine trunk diseases in China.

Figure 4.14 Morphological characterization of *Fusarium hainanense* (JZB3110199)

Figure 4.14 a Upper view of the colony on PDA. b Reverse view of the colony on PDA. c Sporodochia formed on the surface of carnation leaves. d Conidiophores. e–i Macroconidia. Scale bars: c = 50 μm , d–i = 10 μm .

Fusarium lacertarum Subrahm. [as ‘laceratum’], Mykosen 26 (9): 478 (1983)
Index Fungorum: IF534970; Facesoffungi number: FoF 14336

Asexual morph: On CLA, *conidiophores* branched or unbranched. *Macroconidia* variable in size, fusiform to falcate, straight to slightly curved, with foot-shaped basal cells, tapering to hooked apical cells, 2–5-septate, 19–36 \times 3–5 μm ($\bar{x} \pm \text{SD} = 27.8 \pm 4.2 \times 4.2 \pm 0.5 \mu\text{m}$, $n = 50$) (Figure 4.15). *Chlamydoconidia* were in abundance and present in chains. Sexual morph: Not observed.

Culture characteristics – Colonies on PDA were white with floccose aerial mycelium, turning pale buff in the centre. Colonies reached 7.4 cm diam after 4 days at 25°C (Figure 4.15).

Material Examined – China, Shannxi Province, Weinan City, on the root of *Vitis vinifera*, 29 June 2021, Wei Zhang (Inactive dry cultures JZBH3110201), living cultures JZB3110201.

Notes – In the multi-locus phylogenetic analysis, one isolate clustered with *F. lacertarum* with 78% bootstrap value and 0.97 BYPP (Figure 4.11). *Fusarium lacertarum* was isolated from *Capsicum* in China (Wang et al., 2019) and reported to cause cladode rot in *Nopalea cochenillifera* in Brazil (Santiago et al., 2018) and the head blight on sorghum in North Carolina (Beacorn & Thiessen, 2021). This is the first report of *F. lacertarum* associated with grapevine trunk diseases in the world.

Figure 4.15 Morphological characterization of *Fusarium lacertarum* (JZB3110201)

Figure 4.15 a Upper view of the colony on PDA. b Reverse view of the colony on PDA. c Conidiophores. d–f Macroconidia. Scale bars: c = 20 μ m, d–f = 10 μ m.

Fusarium oxysporum Schltdl., Fl. berol. (Berlin) 2: 139 (1824)

Index Fungorum: IF218372; Facesoffungi number: FoF 03824

Description – see Lombard et al. (2019)

Material Examined – China, Hebei Province, Qinhuangdao City, Changli County, on the root of *Vitis vinifera*, 18 October 2021, Linna Wu and Xinghong Li, living cultures JZB3110181, JZB3110184; *ibid.*, on the root of *Vitis vinifera*, 13 November 2021, Linna Wu and Xinghong Li, living cultures JZB3110185, JZB3110186; *ibid.*, on the trunk of *Vitis vinifera*, 18 October 2021, Linna Wu and Xinghong Li, living cultures JZB3110182, JZB3110183; China, Yunnan Province, Binchuan County, on the root of *Vitis vinifera*, 23 July 2021, Linna Wu and Xinghong Li, living cultures JZB3110187; China, Fujian Province, Longyan City, Shanghang County, on the root of *Vitis vinifera*, 19 January 2022, Linna Wu and Xinghong Li, living cultures JZB3110188, JZB3110189.

Notes – In the multi-locus phylogenetic analysis, nine isolates clustered with *F. oxysporum* with 100% ML bootstrap value and 1.0 BYPP (Figure 4.11). *Fusarium oxysporum* is reported to be associated with grapevine decline and dieback in Australia (Highet & Nair, 1995; Castillo-Pando et al., 2001), vascular wilt in Egypt (Ziedan et al., 2011) and withered rotten grapes in Italy (Lorenzini & Zapparoli, 2015), or as an endophyte in Spain (González & Tello, 2011), and saprotrophic fungi in China (Jayawardena et al., 2018).

Neocosmospora E.F. Sm., Bull. U.S. Department of Agriculture 17: 45 (1899)

Neocosmospora falciformis (Carrión) L. Lombard & Crous, Stud. Mycol. 80: 227 (2015)

Index Fungorum: IF810958; Facesoffungi number: FoF 14357

Asexual morph: *Sporodochia* formed abundantly on CLA. *Conidiophores* verticillately branched; phialides subcylindrical to doliiform, smooth- and thin-walled. *Macroconidia* slightly fusoid to falcate, with blunt apical cells and barely notched basal cell, 2–5-septate, 25–46 × 5–8 µm, ($\bar{x} \pm SD = 39.4 \pm 4.7 \times 5.9 \pm 0.7$ µm, n = 50). *Microconidia* ellipsoidal to subcylindrical, straight or gently curved, 0–1-septate. *Chlamydospores* were globose to subglobose, single-celled, terminal and rough-walled (Figure 4.16). Sexual morph: Not observed.

Culture characteristics – Colonies on PDA were white to pale-cream with sparse floccose aerial mycelium, growing in concentric rings, reverse beige. Colonies reached 4.9 cm diam. after 4 days at 25°C (Figure 4.16).

Material Examined – China, Shaanxi Province, Weinan City, on the root of *Vitis vinifera*, 29 June 2021, Wei Zhang (Inactive dry cultures JZBH3620005), living cultures JZB3620005; China, Ningxia Province, Yinchuan City, on the trunk of *Vitis vinifera*, 15 September 2021, Weizhang and Xinghong Li (Inactive dry cultures JZBH3620006, JZBH3620007), living cultures JZB3620006, JZB3620007; China, Beijing City, on the root of *Vitis vinifera*, 11 September 2021, Linna Wu and Xinghong Li (Inactive dry cultures JZBH3620008–JZBH3620011), living cultures JZB3620008–JZB3620011.

Notes – In the multi-locus phylogenetic analysis, seven isolates clustered with *N. falciformis* with 52% ML bootstrap value and 1.0 BYPP (Figure 4.11). *Neocosmospora falciformis* (former *Fusarium falciforme*) was reported to cause root rot in *Weigela florida* and *Dioscorea polystachya* in China (Shen et al., 2020; Zhang et al., 2020), foot rot and wilt in tomatoes and maize stalk rot in Mexico (Vega-Gutiérrez et al., 2019; Douriet-Angulo et al., 2019). This is the first report of *N. falciformis* associated with grapevine trunk diseases in the world.

Figure 4.16 Morphological characterization of *Neocosmospora falciformis* (JZB3620005)

Figure 4.16 a Upper view of the colony on PDA. b Reverse view of the colony on PDA. c Sporodochia formed on the surface of carnation leaves. d–f Microconidia. g Chlamydospore. h Conidiophores and phialides. i–n Macroconidia. Scale bars: c–n = 10 μ m.

Neocosmospora solani (Mart.) L. Lombard & Crous, in Lombard, van der Merwe, Groenewald & Crous, Stud. Mycol. 80: 228 (2015)

Index Fungorum: IF810964; Facesoffungi number: FoF 14358

Asexual morph: Cream sporodochia formed abundantly on CLA. *Conidiophores* branched. *Macroconidia* are relatively wide falcate or fusoid, straight or slightly curved with blunt apical cells and notched or round basal cell, 3–5-septate, 25–58 \times 5–7 μ m ($\bar{x} \pm SD = 47.5 \pm 6.4 \times 6.1 \pm 0.5 \mu$ m, n = 50) (Figure 4.17). Sexual morph: Not observed.

Culture characteristics – Colonies on PDA were white to cream with sparse aerial mycelium, growing in concentric rings. Colonies reached 4.5 cm diam after 4 days at 25°C (Figure 4.17).

Material Examined – China, Fujian Province, Longyan City, Shanghang County, on the root of *Vitis vinifera*, 19 January 2022, Linna Wu and Xinghong Li (Inactive dry cultures JZBH3620001–JZBH3620003), living cultures JZB3620001–JZB3620003; China, Hebei Province, Qinhuangdao City, Changli County, on the root of *Vitis vinifera*, 13 November 2021, Linna Wu and Xinghong Li (JZBH3620004), living cultures JZB3620004.

Notes – In the multi-locus phylogenetic analysis, four isolates clustered with *N. solani* with 92% ML bootstrap support values and 1.0 BYPP (Figure 4.11). *Neocosmospora solani* (former *Fusarium solani*) is an important pathogen and the most common species with a wide host range (Sandoval-Denis et al., 2019). This species was isolated from grapevine in Brazil and India (Jayawardena et al., 2018). This is the first report of *N. solani* associated with grapevine trunk diseases in China.

Figure 4.17 Morphological characterization of *Neocosmospora solani* (JZB3620004)

Bisifusarium L. Lombard, Crous & W. Gams, in Lombard, van der Merwe, Groenewald & Crous, Stud. Mycol. 80: 223 (2015)

Bisifusarium delphinoides (Schroers, Summerb., O'Donnell & Lampr.) L. Lombard & Crous, in Lombard, van der Merwe, Groenewald & Crous, Stud. Mycol. 80: 224 (2015)

Index Fungorum: IF810228; Facesoffungi number: FoF 14364

Description – See Schroers (2009)

Material Examined – China, Hebei Province, Zhangjiakou City, Huailai County, on the root of *Vitis vinifera*, 9 July 2021, Linna Wu and Xinghong Li (Inactive dry cultures JZBH3630001, JZBH3630002), living cultures JZB3630001, JZB3630002.

Notes – In the multi-locus phylogenetic analysis, two isolates clustered with *B. delphinoides* with 100% ML bootstrap value and 1.0 BYPP (Figure 4.11). The species was isolated from *Citrus* in the USA (Schroers et al., 2009), oriental melon (nonpathogenic) in Korea (Seo & Kim, 2017), and as putative mycoparasites of *Plasmopara viticola*, which cause downy mildew in grapevines (Ghule et al., 2018). This is the first report of *B. delphinoides* associated with grapevine trunk diseases in China.

Diaporthaceae Höhn. ex Wehm., Am. J. Bot. 13: 638 (1926)

Diaporthe Fuckel, Fungi rhenani exsic., suppl., fasc. 5: no. 1988 (1867)

The genus *Diaporthe* comprises pathogenic, endophytic and saprobic species with wide host ranges and geographic distributions (Norphanphoun et al., 2022). The taxonomy of the species in this genus is complicated because of cryptic diversification and phenotypic plasticity within the genus (Udayanga et al., 2014). In this study, 39 isolates belonging to *Diaporthe* species were identified. For taxonomic treatments, we follow Norphanphoun et al. (2022).

Diaporthe eres Nitschke, Pyrenomyc. Germ. 2: 245 (1870)

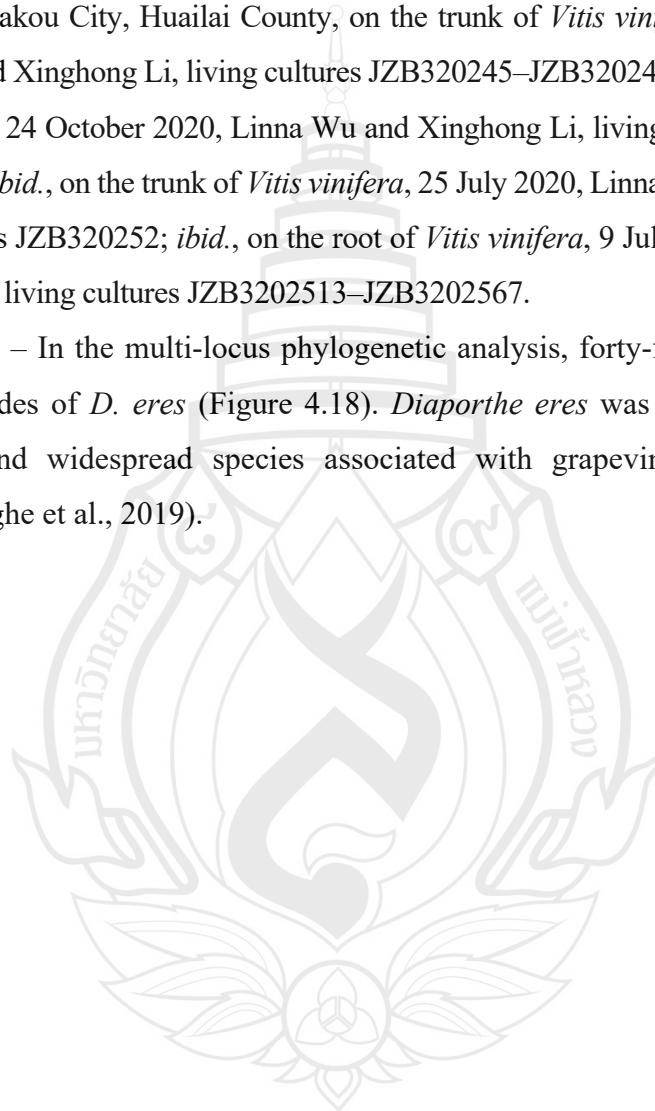

Index Fungorum: IF172054; Facesoffungi number: FoF 02182

Description – See Udayanga et al. (2014)

Material Examined – China, Beijing City, on the trunk of *Vitis vinifera*, 11 September 2021, Linna Wu and Xinghong Li, living cultures JZB320221–JZB320228, JZB320232–JZB320235; *ibid.*, on the root of *Vitis vinifera*, 11 September 2021, Linna Wu and Xinghong Li, living cultures JZB320229–JZB320231, JZB320236; China, Hebei

Province, Qinhuangdao City, Changli County, on the trunk of *Vitis vinifera*, 13 November 2021, Linna Wu and Xinghong Li, living cultures JZB320237–JZB320239; *ibid.*, Changli County, on the trunk base of *Vitis vinifera*, 13 November 2021, Linna Wu and Xinghong Li, living cultures JZB320240, JZB320241; *ibid.*, on the root of *Vitis vinifera*, 13 November 2021, Linna Wu and Xinghong Li, living cultures JZB320242–JZB320244; *ibid.*, Zhangjiakou City, Huailai County, on the trunk of *Vitis vinifera*, 22 August 2021, Linna Wu and Xinghong Li, living cultures JZB320245–JZB320247; *ibid.*, on the trunk of *Vitis vinifera*, 24 October 2020, Linna Wu and Xinghong Li, living cultures JZB320248–JZB320251; *ibid.*, on the trunk of *Vitis vinifera*, 25 July 2020, Linna Wu and Xinghong Li, living cultures JZB320252; *ibid.*, on the root of *Vitis vinifera*, 9 July 2021, Linna Wu and Xinghong Li, living cultures JZB3202513–JZB3202567.

Notes – In the multi-locus phylogenetic analysis, forty-four isolates clustered with two clades of *D. eres* (Figure 4.18). *Diaporthe eres* was regarded as the most prominent and widespread species associated with grapevine dieback in China (Manawasinghe et al., 2019).

Figure 4.18 Maximum likelihood analysis of combined ITS, *tub2*, *cal* and *tef1* sequence data of *Diaporthe* species

Figure 4.18 *Diaporthella corylina* (CBS 121124) was used as the outgroup taxon. The best scoring RAxML tree with a final likelihood value of -17167.323573 was presented here. The matrix had 1137 distinct alignment patterns, with 18.64% undetermined characters or gaps. Estimated base frequencies were as follows: A = 0.216280, C = 0.316586, G = 0.241042, T = 0.226092; substitution rates AC = 1.266614, AG = 3.539624, AT = 1.228789, CG = 1.147037, CT = 4.911515, GT = 1.000000; gamma distribution shape parameter $\alpha = 0.721142$. ML bootstrap support values $\geq 50\%$ (BT) and Bayesian posterior probabilities ≥ 0.90 (BYPP) are shown near the nodes. The scale bar indicates 0.2 changes per site. Isolates from the current study are in red and type specimens are in bold.

Diaporthe unshiuensis F. Huang, K.D. Hyde & Hong Y. Li, in Huang, Udayanga, Mei, Fu, Hyde & Li, *Fungal Biology* 119(5): 344 (2015)

Index Fungorum: IF810845; Facesoffungi number: FoF 09422

Description – See Huang et al. (2015)

Material Examined – China, Fujian Province, Longyan City, Shanghang County, on the trunk of *Vitis vinifera*, 19 January 2022, Linna Wu and Xinghong Li, living cultures JZB320258, JZB320259.

Notes – In the multi-locus phylogenetic analysis, two isolates clustered with *D. unshiuensis* with 100% ML bootstrap value and 1.0 BYPP (Figure 4.18). *Diaporthe unshiuensis* has been recorded to be associated with Diaporthe dieback in China (Manawasinghe et al., 2019).

Togniniaceae Réblová, L. Mostert, W. Gams & Crous, *Stud. Mycol.* 50(2): 540 (2004)

Phaeoacremonium W. Gams, Crous & M.J. Wingf., *Mycologia* 88 (5): 789 (1996)

Phaeoacremonium spp. are common pathogens on stems and branches on a wide range of woody hosts, especially on grapevine (Gramaje et al., 2015). In 2021, *Phaeoacremonium minimum* was first reported as a pathogen of Esca disease in China (Ye et al., 2020). In this study, we follow Ye et al. (2021b) for taxonomic treatments.

Phaeoacremonium iranianum L. Mostert, Gräfenhan, W. Gams & Crous, in Mostert, Groenewald, Summerbell, Gams & Crous, Stud. Mycol. 54: 83 (2006)

Index Fungorum: IF500227; Facesoffungi number: FoF 14338

Asexual morph: *Conidiophores* unbranched, erect. *Phialides* mostly monophialidic, have three types: type I phialides the shortest, cylindrical; type II phialides medium sized, elongate-ampulliform to navicular; type III phialides were long, subcylindrical to navicular, some tapering towards the apex to form a thin neck. *Conidia* oblong-ellipsoidal, $4\text{--}9 \times 2\text{--}3 \mu\text{m}$ ($\bar{x} \pm \text{SD} = 6.1 \pm 1.2 \times 2.3 \pm 0.3 \mu\text{m}$, $n = 50$) (Figure 4.19). Sexual morph: Not observed.

Culture characteristics – Colonies on PDA felty, olive-brown, in reverse dark brown. Colonies reached 7.7 cm diam after 28 days at 25°C (Figure 4.19).

Material Examined – China, Hebei Province, Changli County, on the trunk of *Vitis vinifera*, 18 October 2021, Linna Wu and Xinghong Li (Inactive dry cultures JZBH3190013, JZBH3190014), living cultures JZB3190013, JZB3190014.

Notes – In the multi-locus phylogenetic analysis, two isolates clustered with *P. iranianum* with 100% ML bootstrap value and 1.0 BYPP (Figure 4.20). *Phaeoacremonium iranianum* was initially isolated from kiwi fruit and grapevines in Iran and Italy (Mostert et al., 2006) and reported to cause Esca disease of grapevine in Canada, Italy, South Africa and Spain (Gramaje et al., 2015). This is the first report of *P. iranianum* associated with grapevine trunk diseases in China.

Figure 4.20 *Pleurostoma richardsiae* (CBS 270.33) was used as the outgroup taxon. The best scoring RAxML tree with a final likelihood value of -10031.367491 was presented. The matrix had 622 distinct alignment patterns, with 12.24% of undetermined characters or gaps. Estimated base frequencies were as follows: A = 0.216115, C = 0.316660, G = 0.225016, T = 0.242209; substitution rates AC = 1.424857, AG = 5.577572, AT = 1.486155, CG = 1.182568, CT = 5.200674, GT = 1.000000;

gamma distribution shape parameter $\alpha = 2.279586$. ML bootstrap support values $\geq 50\%$ (BT) and Bayesian posterior probabilities ≥ 0.90 (BYPP) are shown near the nodes. The scale bar indicates 0.07 changes per site. Isolates from the current study are in red and type specimens are in bold.

Schizoparmaceae Rossman, D.F. Farr & Castl. [as 'Schizoparmeaceae'], Mycoscience 48 (3): 137 (2007)

Coniella Höhn., Ber. dt. bot. Ges. 36 (7): 316 (1918)

For taxonomic treatments, we follow Chethana et al. (2017).

Coniella vitis Chethana, J.Y. Yan, X.H. Li & K.D. Hyde, in Chethana, Zhou, Zhang, Liu, Xing, Hyde, Yan & Li, Pl. Dis. 101 (12): 2129 (2017)

Index Fungorum: IF819365; Facesoffungi number: FoF 02722

Description – See Chethana et al. (2017)

Material Examined – China, Beijing City, on the trunk of *Vitis vinifera*, 11 September 2021, Linna Wu and Xinghong Li, living cultures JZB3700081, JZB3700082; China, Hebei Province, Changli County, on the trunk of *Vitis vinifera*, 18 October 2021, Linna Wu and Xinghong Li, living cultures JZB3700083, JZB3700084; *ibid.*, on the root of *Vitis vinifera*, 18 October 2021, Linna Wu and Xinghong Li, living cultures JZB3700085–JZB3700087.

Notes – In the multi-locus phylogenetic analysis, seven isolates clustered with *C. vitis* with 85% ML bootstrap values and 0.97 BYPP (Figure 4.21). *Coniella vitis* was described as a novel species causing white rot in grapevine berries in China (Chethana et al., 2017).

Figure 4.21 Phylogenetic tree generated by maximum likelihood analysis of combined ITS, *his*, LSU and *tef1* sequence data of *Coniella* species

Figure 4.21 A–C leaf symptoms in the field. D–F leaf spot samples. *Melanconiella* sp. (CBS 110385) was used as the outgroup taxon. The best-scoring RAxML tree with a final likelihood value of -12111.406531 was presented. The matrix had 688 distinct alignment patterns, with 21.86% of undetermined characters or gaps. Estimated base frequencies were as follows: A = 0.245494, C = 0.247696, G = 0.255443, T = 0.251367; substitution rates AC = 1.306162, AG = 2.579472, AT = 1.571029, CG = 0.884497,

CT = 5.752512, GT = 1.000000; gamma distribution shape parameter $\alpha = 0.397636$. ML bootstrap support values $\geq 50\%$ (BT) and Bayesian posterior probabilities ≥ 0.90 (BYPP) are shown near the nodes. The scale bar indicates 0.07 changes per site. Isolates from the current study are in red and type specimens are in bold.

Sporocadaceae Corda [as ‘Sporocadeae’], Icon. fung. (Prague) 5: 34 (1842)

Species of Sporocadaceae are endophytes, phytopathogens or saprobes with a wide host range, which are characterized by producing appendaged conidia (Liu et al., 2019). *Neopestalotiopsis* and *Pestalotiopsis*, generally known as Pestalotioid fungi, are important pathogens causing postharvest fruit rot and trunk diseases on grapevines in many countries (Jayawardena et al., 2015; Maharachchikumbura et al., 2016). In this study, sixteen isolates were obtained from Sporocadaceae belonging to *Pestalotiopsis*, *Neopestalotiopsis* and *Bartalinia*, representing five species. For taxonomic treatments of Sporocadaceae, we follow Tibpromma et al. (2020) and Li et al. (2021).

Pestalotiopsis Steyaert, Bull. Jard. bot. État Brux. 19: 300 (1949)

Pestalotiopsis kenyana Maharachch., K.D. Hyde & Crous, in Maharachchikumbura, Hyde, Groenewald, Xu & Crous, Stud. Mycol. 79: 166 (2014)

Index Fungorum: IF809741; Facesoffungi number: FoF 06981

Asexual morph: *Conidiogenous* cells discrete, lageniform to subcylindrical, hyaline. *Conidia* fusoid to subcylindrical, straight to slightly curved, 4-septate, $23\text{--}29 \times 7\text{--}9 \mu\text{m}$ ($\bar{x} \pm \text{SD} = 25.2 \pm 1.7 \times 7.7 \pm 0.5 \mu\text{m}$, $n = 50$); basal cell conic to obconic, hyaline; three median cells doliiform, wall verruculose concolourous, brown, septa darker than the rest of the cell; apical cell subcylindrical, hyaline, with two to three tubular appendages arising from the apex of the apical cell, one filiform, basal appendage (Figure 4.22). Sexual morph: Not observed.

Culture characteristics – Colonies on PDA white with wavy edge. Colonies reached 6.7 cm diam after 5 days at 25°C (Figure 4.22).

Material Examined – China, Fujian Province, Longyan City, Shanghang County, on the trunk of *Vitis vinifera*, 4 January 2022, Linna Wu and Xinghong Li (Inactive dry cultures JZBH340076–JZBH340078), living cultures JZB340076–JZB340078.

Notes – In the multi-locus phylogenetic analysis, three isolates clustered with *P. kenyana* with 94% ML bootstrap value and 1.0 BYPP (Figure 4.23). *Pestalotiopsis*

kenyana was reported on *Camellia sinensis* in China (Liu et al., 2017). This is the first report of this species associated with grapevine trunk diseases in the world.

Figure 4.22 Morphological characterization of *Pestalotiopsis kenyana* (JZB340076)

Figure 4.22 a Upper view of the colony on PDA. b Reverse view of the colony on PDA. c Conidiogenous cells and conidia. d–g Conidia. Scale bars: c–g =10 μ m.

Figure 4.23 Phylogenetic tree generated by maximum likelihood analysis of combined ITS, *tub2* and *tefl* sequence data of *Pestalotiopsis* species

Figure 4.23 *Neopestalotiopsis magna* (MFLUCC 12-0652) was used as the outgroup taxon. The best-scoring RAxML tree with a final likelihood value of -9698.046952 was presented. The matrix had 733 distinct alignment patterns, with 15.42% of undetermined characters or gaps. Estimated base frequencies were as follows: A = 0.239513, C = 0.293756, G = 0.215210, T = 0.251521; substitution rates AC = 1.226778, AG = 3.764525, AT = 1.325866, CG = 1.211293, CT = 5.305853, GT = 1.000000; gamma distribution shape parameter $\alpha = 0.597712$. ML bootstrap support values $\geq 50\%$ (BT) and Bayesian posterior probabilities ≥ 0.90 (BYPP) are shown near the nodes. The scale bar indicates 0.04 changes per site. Isolates from the current study are in red and type specimens are in bold.

Pestalotiopsis rhodomyrtus Y. Song, K. Geng, K.D. Hyde & Yong Wang, Phytotaxa 126: 27. 2013.

Index Fungorum: IF846110; Facesoffungi number: FoF 09398

Asexual morph: *Conidiomata* scattered, black. *Conidiogenous cells* discrete, filiform, hyaline. *Conidia* fusoid, straight or slightly curved, 4-septate, $25\text{--}32 \times 5\text{--}7 \mu\text{m}$ ($\bar{x} \pm \text{SD} = 28.6 \pm 1.9 \times 6.0 \pm 0.5 \mu\text{m}$, $n = 50$); basal cell conic to obconic, hyaline; three median cells doliiiform, concolorous, brown, septate and periclinal walls darker than the rest of the cell, verruculose; apical cell subcylindrical to obconic, hyaline, with 2–3 tubular appendages arising from the apex of the apical cell, with one filiform, basal appendage (Figure 4.24). Sexual morph: Not observed.

Culture characteristics – Colonies on PDA were white with crenate edge, reverse light orange with white margin (Figure 4.24). Colonies reached 6.9 cm diam after 5 days at 25°C.

Material Examined – China, Fujian Province, Longyan City, Shanghang County, on the trunk of *Vitis vinifera*, 19 January 2022, Linna Wu and Xinghong Li (Inactive dry cultures JZBH340080–JZBH340081), living cultures JZB340080–JZB340081.

Notes – In the multi-locus phylogenetic analysis, two isolates clustered with *P. rhodomyrtus* with 100% ML bootstrap value and 1.0 BYPP (Figure 4.23). *Pestalotiopsis rhodomyrtus* was reported on *Rhodomyrtus tomentosa* and *Camellia sinensis* in China (Liu et al., 2017; Song et al., 2013). This is the first report of this species associated with grapevine trunk diseases in the world.

Figure 4.24 Morphological characterization of *Pestalotiopsis rhodomyrtus* (JZB340080)

Pestalotiopsis adusta (Ellis & Everh.) Steyaert, Trans. Br. mycol. Soc. 36(2): 82 (1953)

Index Fungorum: IF302600; Facesoffungi number: FoF 14323

Asexual morph: *Conidiomata* globose, black. *Conidiogenous cells* discrete, filiform, hyaline. *Conidia* fusiform to ellipsoid, straight or slightly curved, 4-septate, 17–27 \times 5–7 μm ($\bar{x} \pm \text{SD} = 21.7 \pm 2.0 \times 5.8 \pm 0.6 \mu\text{m}$, n = 50); basal cell obtuse, hyaline; three median cells doliiform, concolorous, olivaceous, septate and periclinal walls

darker than the rest of the cell, verruculose; apical cell obconic, hyaline, with 2–3 tubular appendages arising from the apex of the apical cell, with one filiform, basal appendage (Figure 4.25). Sexual morph: Not observed.

Culture characteristics – Colonies on PDA white with undulate edge, reverse orange (Figure 4.25). Colonies reached 8.0 cm diam. after 5 days at 25°C.

Material Examined – China, Fujian Province, Longyan City, Shanghang County, on the root of *Vitis vinifera*, 4 January 2022, Linna Wu and Xinghong Li (Inactive dry cultures JZBH340079), living cultures JZB340079.

Notes – In the multi-locus phylogenetic analysis, one isolate clustered with *P. adusta* with 99% ML bootstrap value and 1.0 BYPP (Figure 4.23). *Pestalotiopsis adusta* was reported to cause leaf spot on raspberry and mongo in China (Yan et al., 2019; Shu et al., 2020). This is the first report of the species associated with grapevine trunk diseases in the world.

Figure 4.25 Morphological characterization of *Pestalotiopsis adusta* (JZB340079)

Figure 4.25 a Upper view of the colony on PDA. b Reverse view of the colony on PDA. c Conidiomata sporulating on PDA. d, e Conidiogenous cells and conidia. f–k Conidia. Scale bars: c = 100 μm , d–k = 10 μm .

Neopestalotiopsis Maharachch., K.D. Hyde & Crous, in Maharachchikumbura, Hyde, Groenewald, Xu & Crous, Stud. Mycol. 79: 135 (2014)

Neopestalotiopsis rosae Maharachch., K.D. Hyde & Crous, in Maharachchikumbura, Hyde, Groenewald, Xu & Crous, Stud. Mycol. 79: 147 (2014)

Index Fungorum: IF809777; Facesoffungi number: FoF 03890

Description – See Maharachchikumbura et al. (2014)

Material Examined – China, Yunnan Province, Binchuan County, on the trunk of *Vitis vinifera*, 23 July 2021, Linna Wu and Xinghong Li, living culture JZB340082; *ibid.*, on the root of *Vitis vinifera*, 23 July 2021, Linna Wu and Xinghong Li, living culture JZB340083.

Notes – In the multi-locus phylogenetic analysis, two isolates clustered with *N. rosae* with 70% ML bootstrap value and 1.0 BYPP (Figure 4.26). The morphological characteristics of these isolates were similar to the type of *N. rosae* (CBS 101057) (Maharachchikumbura et al., 2014). *Neopestalotiopsis rosae* was reported to cause grape rot in the USA (Cosseboom & Hu, 2021). This is the first report of *N. rosae* associated with grapevine trunk diseases in China.

Figure 4.26 Phylogenetic tree generated by maximum likelihood analysis of combined ITS, *tub2* and *tefl* sequence data of *Neopestalotiopsis* species

Figure 4.26 *Pestalotiopsis trachicarpicola* (OP068T) was used as the outgroup taxon. The best-scoring RAxML tree with a final likelihood value of -4690.057697 was presented. The matrix had 220 distinct alignment patterns, with 9.61% of undetermined characters or gaps. Estimated base frequencies were as follows: A = 0.237087, C =

0.273572, G = 0.213431, T = 0.275910; substitution rates AC = 0.728700, AG = 4.270377, AT = 1.372478, CG = 0.528762, CT = 5.131524, GT = 1.000000; gamma distribution shape parameter α = 0.791052. ML bootstrap support values $\geq 50\%$ (BT) and Bayesian posterior probabilities ≥ 0.90 (BYPP) are shown near the nodes. The scale bar indicates 0.04 changes per site. Isolates from the current study are in red and type specimens are in bold.

Bartalinia Tassi, Bulletin Labor. Orto Bot. de R. Univ. Siena 3: 4 (1900)

Bartalinia kevinhydei Doilom, Tibpromma & D.J. Bhat, in Tibpromma, Karunarathna, Mortimer, Xu, Doilom & Lumyong, Phytotaxa 474(1): 32 (2020)

Index Fungorum: IF557718; Facesoffungi number: FoF 08146

Asexual morph: *Conidiomata* subglobose. *Conidiogenous cells* ampulliform to subcylindrical, hyaline. *Conidia* subcylindrical, straight or slightly curved, 4-septate, 19–26 × 3–6 μm ($\bar{x} \pm \text{SD} = 21.4 \pm 1.7 \times 4.7 \pm 0.6 \mu\text{m}$, n = 50); basal cell conic, hyaline, sometimes pale brown, paler than second to fourth cells; three median cells doliiiform, concolorous, pale brown, septate with periclinal walls darker than the rest of the cell; apical cell conical, hyaline, with 3 tubular appendages arising from the apex of the apical cell with one filiform, basal appendage (Figure 4.27). Sexual morph: Not observed.

Culture characteristics – Colonies on PDA were yellow-brown in the centre and cream color at edge (Figure 4.27). Colonies reached 6.2 cm diam after 5 days at 25°C.

Material Examined – China, Yunnan Province, Binchuan County, on the trunk of *Vitis vinifera*, 23 July 2021, Linna Wu and Xinghong Li (Inactive dry cultures JZBH3640001, JZBH3640002), living cultures JZB3640001, JZB3640002; *ibid.*, Ningxia Province, Yinchuan City, on the trunk of *Vitis vinifera*, 15 September 2021, Linna Wu and Xinghong Li (Inactive dry cultures JZBH3640003, JZBH3640004), living cultures JZB3640003, JZB3640004; *ibid.*, Hebei Province, Changli County, on the trunk of *Vitis vinifera*, 18 October 2021, Linna Wu and Xinghong Li (Inactive dry cultures JZBH3640005, JZBH3640006), living cultures JZB3640005, JZB3640006; *ibid.*, Beijing City, Fangshan District, on the trunk of *Vitis vinifera*, 11 September 2021, Linna Wu and Xinghong Li (Inactive dry cultures JZBH3640007, JZBH3640008), living cultures JZB3640007, JZB3640008.

Notes – In the multi-locus phylogenetic analysis, eight isolates clustered with *B. kevinhydei* with 67% ML bootstrap value and 1.0 BYPP (Figure 4.28). *Bartalinia kevinhydei* is a new leaf-spot causing fungus on teak from Northern Thailand (Tibpromma et al., 2020). This is the first report of *B. kevinhydei* associated with grapevine trunk diseases in the world.

Figure 4.27 Morphological characterization of *Bartalinia kevinhydei* (JZB3640003)

Figure 4.27 a Upper view of the colony on PDA. b Reverse view of the colony on PDA. c Conidiomata sporulating on PDA. d, e Conidiogenous cells and conidia. f, g Conidia. Scale bars: c = 100 μm , d–g = 10 μm .

Figure 4.28 Phylogenetic tree generated by maximum likelihood analysis of combined ITS and LSU sequence data of *Bartalinia* species

Figure 4.28 *Pestalotiopsis malayana* (CBS 102220) was used as outgroup taxon. The best scoring RAxML tree with a final likelihood value of -2455.231222 was presented. The matrix had 64 distinct alignment patterns, with 9.62% of undetermined characters or gaps. Estimated base frequencies were as follows: A = 0.259785, C = 0.205067, G = 0.256605, T = 0.278543; substitution rates AC = 0.000100, AG = 6.135642, AT = 5.163560, CG = 7.199006, CT = 22.594137, GT = 1.000000; gamma distribution shape parameter $\alpha = 1000.000000$. ML bootstrap support values $\geq 50\%$ (BT) and Bayesian posterior probabilities ≥ 0.95 (BYPP) are shown near the nodes. The scale bar indicates 0.009 changes per site. Isolates from the current study are in red and type specimens are in bold.

Glomerellaceae Locq. ex Seifert & W. Gams, in Zhang, Castlebury, Miller, Huhndorf, Schoch, Seifert, Rossman, Rogers, Kohlmeyer, Volkmann-Kohlmeyer & Sung, *Mycologia* 98(6): 1083 (2007) [2006]

Colletotrichum Corda, in Sturm, *Deutschl. Fl.*, 3 Abt. (Pilze Deutschl.) 3(12): 41 (1831)

Colletotrichum is the only genus in Glomerellaceae and is regarded as one of the top 10 phytopathogenic fungal genera in the world, causing anthracnose on leaves, fruits, stems and other more organs (Dean et al., 2012; Liu et al., 2022). In this study, we follow Liu et al. (2022) for taxonomic treatments.

Colletotrichum viniferum Li J. Peng, L. Cai, K.D. Hyde & Zi Y. Ying, *Mycoscience* 54(1): 36 (2013)

Index Fungorum: IF563086; Facesoffungi number: FoF 03600

Description – See Peng et al. (2013)

Material Examined – China, Fujian Province, Longyan City, Shanghang County, on the shoot of *Vitis vinifera*, 20 May 2021, Linna Wu and Xinghong Li, living cultures JZB330319–JZB330322; *ibid.*, Beijing City, on the trunk of *Vitis vinifera*, 11 September 2021, Linna Wu and Xinghong Li, living cultures JZB330323, JZB330324.

Notes – In the multi-locus phylogenetic analysis, six isolates clustered with *C. viniferum* with 100% ML bootstrap value and 1.0 BYPP (Figure 4.29). *Colletotrichum viniferum* was reported to cause fruit anthracnose and leaf lesions of grapevines in China (Peng et al., 2013; Yan et al., 2015).

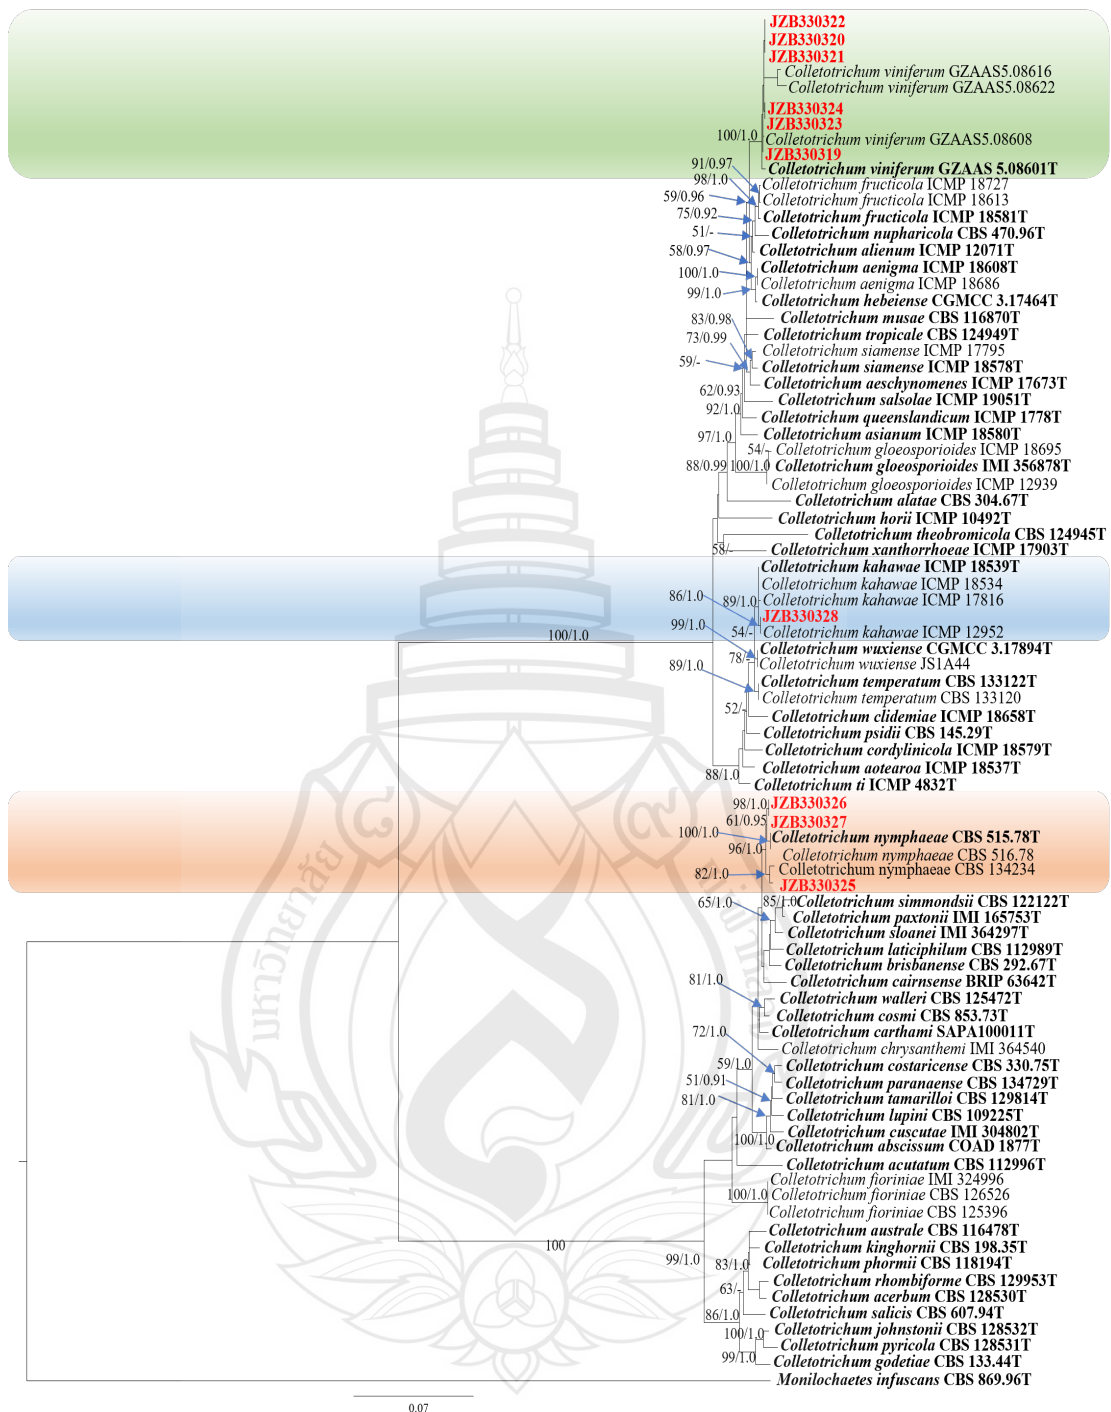

Figure 4.29 Phylogenetic tree generated by maximum likelihood analysis of combined ITS, *gapdh*, *act*, *chs* and *tub2* sequence data of *Colletotrichum* species

Figure 4.29 *Monilochaetes infuscans* (CBS 869.96) was used as the outgroup taxon. The best scoring RAxML tree with a final likelihood value of -11791.239474 was presented. The matrix had 941 distinct alignment patterns, with 13.45% of

undetermined characters or gaps. Estimated base frequencies were as follows: A = 0.232433, C = 0.302405, G = 0.240309, T = 0.224853; substitution rates AC = 1.238239, AG = 3.563826, AT = 1.094851, CG = 0.802739, CT = 5.163031, GT = 1.000000; gamma distribution shape parameter $\alpha = 0.983971$. ML bootstrap support values $\geq 50\%$ (BT) and Bayesian posterior probabilities ≥ 0.95 (BYPP) are shown near the nodes. The scale bar indicates 0.07 changes per site. Isolates from the current study are in red and type specimens are in bold.

Colletotrichum nymphaeae (Pass.) Aa, Netherlands Journal of Plant Pathology, Supplement 1 84(3): 110 (1978)

Index Fungorum: IF311502; Facesoffungi number: FoF 14339

Description – See Damm et al. (2012)

Material Examined – China, Fujian Province, Longyan City, Shanghang County, on the shoot of *Vitis vinifera*, 20 May 2021, Linna Wu and Xinghong Li, living cultures JZB330325; *ibid.*, on the trunk of *Vitis vinifera*, 4 January 2022, Linna Wu and Xinghong Li, living cultures JZB330326, JZB330327.

Notes – In the multi-locus phylogenetic analysis, three isolates clustered with *C. nymphaeae* with 96% ML bootstrap value and 1.0 BYPP (Figure 4.29). *Colletotrichum nymphaeae* was reported to cause twig anthracnose on grapevines in China (Liu et al., 2016).

Colletotrichum kahawae J.M. Waller & Bridge, Mycol. Res. 97(8): 993 (1993)

Index Fungorum: IF360355; Facesoffungi number: FoF 14359

Asexual morph: *Conidiophores* hyaline, one-celled, not branching. *Conidia* cylindrical, 10–15 × 5–8 μm ($\bar{x} \pm \text{SD} = 12.8 \pm 1.1 \times 6.5 \pm 0.6 \mu\text{m}$, n = 50). *Appressoria* spherical, ovoid or slightly irregular (Figure 4.30). Sexual morph: Not observed.

Culture characteristics – Colonies on PDA white to pale grey, reverse dark gray with white margin. Colonies reached 6.5 mm diam. after 5 days at 25°C (Figure 4.30).

Material Examined – China, Yunnan Province, Mile City, on the trunk of *Vitis vinifera*, 9 September 2020, Linna Wu and Xinghong Li (Inactive dry cultures JZBH330328), living cultures JZB330328.

Notes – In the multi-locus phylogenetic analysis, one isolate clustered with *C. kahawae* with 89% ML bootstrap value and 1.0 BYPP (Figure 4.29). *Colletotrichum kahawae* was reported to cause grape ripe rot disease in Brazil (Echeverrigaray et al.,

2020). This is the first report of *C. kahawae* associated with grapevine trunk disease in China.

Figure 4.30 Morphological characterization of *Colletotrichum kahawae* (JZB330328)

Pleosporaceae Nitschke, Verh. naturh. Ver. preuss. Rheinl. 26: 74 (1869)

Alternaria Nees, Syst. Pilze (Würzburg): 72 (1816) [1816-17]

Alternaria widely distributed in various substrates as saprobes, endophytes and pathogens, and has numerous hosts including grapevine (Woudenberg et al., 2013; Tao et al., 2014). In this study, eight isolates belonging to two *Alternaria* species were identified. For taxonomic treatments, we follow Woudenberg et al. (2013).

Alternaria alternata (Fr.) Keissl., Beih. bot. Zbl., Abt. 2 29: 434 (1912)

Index Fungorum: IF119834; Facesoffungi number: FoF 03825

Description – See Woudenberg et al. (2013)

Asexual morph: China, Shanxi Province, Linfen City, on the trunk of *Vitis vinifera*, 23 June 2021, Linna Wu and Xinghong Li, living cultures JZB3180127, JZB3180128; *ibid.*, Hebei Province, Zhangjiakou City, Huailai County, on the trunk of

Vitis vinifera, 9 July 2021, Linna Wu and Xinghong Li, living cultures JZB3180129, JZB3180130; *ibid.*, Qinhuangdao City, Changli County, on the trunk of *Vitis vinifera*, 13 November 2021, Linna Wu and Xinghong Li, living cultures JZB3180131; *ibid.*, Fujian Province, Longyan City, Shanghang County, on the trunk of *Vitis vinifera*, 4 January 2022, Linna Wu and Xinghong Li, living culture JZB3180132.

Notes – In the multi-locus phylogenetic analysis, six isolates clustered in two clades of *A. alternata* with 97% ML bootstrap value and 1.0 BYPP (Figure 4.31). *Alternaria* is a widespread fungus, which includes saprobic, endophytic and pathogenic species. *Alternaria alternata* is a well-known plant pathogen around the world, and is reported to cause grapevine fruit rot and also act as endophytes and saprotrophs on grapevine (Jayawardena et al., 2018).

Figure 4.31 Phylogenetic tree generated by maximum likelihood analysis of combined ITS, *tef1*, *rpb2* and *gapdh* sequence data of *Alternaria* species

Figure 4.31 *Paradendryphiella salina* (CBS 302.84) was used as the outgroup taxon. The best scoring RAxML tree with a final likelihood value of -11419.172816 was presented. The matrix had 820 distinct alignment patterns, with 11.89% of undetermined characters or gaps. Estimated base frequencies were as follows: A = 0.241820, C = 0.277132, G = 0.247459, T = 0.233589; substitution rates AC = 1.364113, AG = 4.480928, AT = 1.081367, CG = 0.860134, CT = 10.450729, GT = 1.000000; gamma distribution shape parameter $\alpha = 0.900455$. ML bootstrap support values $\geq 50\%$ (BT) and Bayesian posterior probabilities ≥ 0.95 (BYPP) are shown near the nodes. The scale bar indicates 0.04 changes per site. Isolates from the current study are in red and type specimens are in bold.

Alternaria longipes (Ellis & Everh.) E.W. Mason, Annot. Acct Fungi rec'd Bur. Mycol. 2(1): 19 (1928)

Index Fungorum: IF269712; Facesoffungi number: FoF 14360

Asexual morph: *Conidiophores* light to dark brown with one or a few regular septa, mostly unbranched. *Conidia* obclavate, brown, with three to eight transverse and zero to two longitudinal or oblique septa, $10\text{--}32 \times 6\text{--}14 \mu\text{m}$ ($\bar{x} \pm \text{SD} = 20.0 \pm 5.3 \times 10.7 \pm 2.0 \mu\text{m}$, $n = 50$), and concatenated in long, sometimes branched chains (Figure 4.32). Sexual morph: Not observed.

Culture characteristics – Colonies on PDA were initially white and became grayish brown over time, reverse dark brown with white margin (Figure 4.32). Colonies reached 6.5 mm diam. after 6 days at 25°C.

Material Examined – China, Fujian Province, Longyan City, Shanghang County, on the trunk of *Vitis vinifera*, 4 January 2021, Linna Wu and Xinghong Li (Inactive dry cultures JZBH3180133, JZBH3180134), living cultures JZB3180133, JZB3180134.

Notes – In the multi-locus phylogenetic analysis, two isolates clustered with *A. longipes* with 100% ML bootstrap value and 1.0 BYPP (Figure 4.31). *Alternaria longipes* has been reported to cause leaf spot disease in tea and some medicinal plants in China (Tan et al., 2012; Yin et al., 2021). This is the first report of *A. longipes* associated with grapevine trunk disease in the world.

Figure 4.32 Morphological characterization of *Alternaria longipes* (JZB3180133)

Figure 4.32 a Upper view of the colony on PDA. b Reverse view of the colony on PDA. c–k Conidia and conidiophores. Scale bars: c = 500 μm , d = 100 μm , e–k = 10 μm .

Hypocreaceae De Not. [as ‘Hypocreacei’], G. bot. ital. 2(1): 48 (1844)

Trichoderma Pers., Neues Mag. Bot. 1: 92 (1794)

Trichoderma is a widespread genus with abilities or potentials to be developed as biocontrol agents, for their potent degradative machinery for decomposition of heterogeneous substrates (Schuster & Schmoll, 2010). In this study, six isolates belonging to three *Trichoderma* species were identified. For taxonomic treatments, we follow Cai et al. (2022).

Trichoderma asperellum Samuels, Lieckf. & Nirenberg, Sydowia 51(1): 81 (1999)

Index Fungorum: IF461012; Facesoffungi number: FoF 14361

Asexual morph: *Conidiophores* tree-like, with repeated, paired branching with a main central branch. Phialides flask-shaped, enlarged in the middle. *Conidia* globose

to oval, green, smooth, $3\text{--}4 \times 2\text{--}3 \mu\text{m}$ ($\bar{x} \pm \text{SD} = 3.2 \pm 0.2 \times 2.8 \pm 0.2 \mu\text{m}$, $n = 50$). *Chlamydozoospores* elliptic or round (Figure 4.33). Sexual morph: Not observed.

Culture characteristics – Colonies on PDA initially whitish, downy, gradually green sporulation spread throughout the whole plate, reverse grayish with the formation of concentric rings (Figure 4.33). Colonies reached 6.0 mm diam. after 2 days at 25°C.

Material Examined – China, Yunnan Province, Binchuan County, on the trunk of *Vitis vinifera*, 23 July 2021, Linna Wu and Xinghong Li (Inactive dry cultures JZBH3360013), living culture JZB3360013; *ibid.*, on the root of *Vitis vinifera*, 23 July 2021, Linna Wu and Xinghong Li (Inactive dry cultures JZBH3360014, JZBH3360015), living cultures JZB3360014, JZB3360015.

Notes – In the multi-locus phylogenetic analysis, three isolates clustered with *T. asperellum* with 98% ML bootstrap value and 1.0 BYPP (Figure 4.34). *Trichoderma asperellum* was reported to isolate from withered grape in Italy (Lorenzini et al., 2016). This is the first report of *T. asperellum* associated with grapevine trunk disease in China.

Figure 4.34 *Protocrea farinosa* (CBS 121551) and *Protocrea pallida* (CBS 299.78) were used as the outgroup taxa. The best-scoring RAxML tree with a final likelihood value of -16356.159894 was presented. The matrix had 916 distinct alignment patterns, with 17.53% of undetermined characters or gaps. Estimated base frequencies were as follows: A = 0.235351, C = 0.280622, G = 0.241553, T = 0.242473;

substitution rates AC = 0.812912, AG = 3.702497, AT = 1.233164, CG = 0.719097, CT = 5.223883, GT = 1.000000; gamma distribution shape parameter $\alpha = 1.063259$. ML bootstrap support values $\geq 50\%$ (BT) and Bayesian posterior probabilities ≥ 0.95 (BYPP) are shown near the nodes. The scale bar indicates 0.05 changes per site. Isolates from the current study are in red and type specimens are in bold.

Trichoderma guizhouense Q.R. Li, McKenzie & Yong Wang bis, in Li, Tan, Jiang, Hyde, McKenzie, Bahkali, Kang & Wang, Mycol. Progr. 12(2): 170 (2012) [2013]

Index Fungorum: IF563664; Facesoffungi number: FoF 07838

Asexual morph: *Conidiophores* verticillate. *Phialides* ampulliform to lageniform, mostly in whorls of 2–3. *Conidia* oval to globose, yellow-green, smooth, $3\text{--}4 \times 2\text{--}3 \mu\text{m}$ ($\bar{x} \pm \text{SD} = 3.2 \pm 0.2 \times 2.8 \pm 0.2 \mu\text{m}$, $n = 50$). *Chlamydospores* elliptic or round, terminal (Figure 4.35). Sexual morph: Not observed.

Culture characteristics – Colonies on PDA cottony, dark green, forming concentric rings. Colonies reached 6.8 mm diam. after 2 days at 25°C (Figure 4.35).

Material Examined – China, Beijing City, on the root of *Vitis vinifera*, 11 September 2021, Linna Wu and Xinghong Li (Inactive dry cultures JZBH3360016, JZBH3360017), living cultures JZB3360016, JZB3360017.

Notes – In the multi-locus phylogenetic analysis, two isolates clustered with *T. guizhouense* with 90% ML bootstrap value and 1.0 BYPP (Figure 4.34). *Tritroderma guizhouense* was initially isolated from soil in Guizhou Province, China (Li et al., 2013). This is the first report of *T. guizhouense* associated with grapevine trunk diseases.

Figure 4.35 Morphological characterization of *Trichoderma guizhouense* (JZB3360016)

Figure 4.35 a Upper view of the colony on PDA. b Reverse view of the colony on PDA. c Conidia. d, e Conidiophores. f phialide. g Chlamydospores. Scale bars: c–g = 10 μ m.

Trichoderma virens (J.H. Mill., Giddens & A.A. Foster) Arx, Beih. Nova Hedwigia 87: 288 (1987)

Index Fungorum: IF128198; Facesoffungi number: FoF 14362

Asexual morph: *Conidiophores* erect, asymmetrical branched. *Phialides* flask-shaped to ampulliform. *Conidia* sub-globose to elliptical, green, smooth, $4\text{--}6 \times 3\text{--}5 \mu\text{m}$ ($\bar{x} \pm \text{SD} = 4.5 \pm 0.4 \times 3.8 \pm 0.3 \mu\text{m}$, $n = 50$). *Chlamydospores* elliptic or round (Figure 4.36). Sexual morph: Not observed.

Culture characteristics – Colonies on PDA initially whitish, gradually became deep green, reverse grayish. Colonies reached 5.9 mm diam. after 2 days at 25°C (Figure 4.36).

Material Examined – China, Hebei Province, Qinhuangdao City, Changli County, on the root of *Vitis vinifera*, 13 November 2021, Linna Wu and Xinghong Li (Inactive dry cultures JZBH3360018), living cultures JZB3360018.

Notes – In the multi-locus phylogenetic analysis, one isolate clustered with *T. virens* with 100% ML bootstrap value and 1.0 BYPP (Figure 4.34). *Trichoderma virens* was commonly isolated from the soil, and also reported as an endophyte of sugarcane and coffee (Romão-Dumaresq et al., 2016; Rodríguez et al., 2021). *Trichoderma virens* was isolated from a 42-year-old grapevine free of grapevine trunk disease symptoms in France (Bruez et al., 2016). This is the first report of *T. virens* associated with grapevine trunk disease in China.

Figure 4.36 Morphological characterization of *Trichoderma virens* (JZB3360018)

Cladosporiaceae Chalm. & R.G. Archibald, Yearbook of Tropical Medicine and Hygiene: 25 (1915)

Cladosporium Link, Mag. Gesell. naturf. Freunde, Berlin 7: 37 (1816) [1815]

Cladosporium is a ubiquitous genus with small conidia in large numbers, spread easily over long distances. *Cladosporium* species are common endophytes, and also

could be secondary invaders after other plant pathogens, causing leaf spots (Bensch et al., 2012). In this study, we follow Bensch et al. (2012) for taxonomic treatments.

Cladosporium tenuissimum Cooke, Grevillea 6(no. 40): 140 (1878)

Index Fungorum: IF145672; Facesoffungi number: FoF 09313

Description – See Bensch et al. 2012

Material Examined – China, Fujian Province, Longyan City, Shanghang County, on the trunk of *Vitis vinifera*, 4 January 2021, Linna Wu and Xinghong Li, living cultures JZB390038, JZB390039.

Notes – In the multi-locus phylogenetic analysis, eight isolates clustered with *C. tenuissimum* with 99% ML bootstrap value and 1.0 BYPP (Figure 4.37). *Cladosporium tenuissimum* was reported as a pathogen causing grapevine fruit rot and/or as an endophytic fungus on grapevines in China (Dissanayake et al., 2018; Jayawardena et al., 2018).

Figure 4.37 Phylogenetic tree generated by maximum likelihood analysis of combined ITS, *tef1* and LSU sequence data of *Cladosporium* species

Figure 4.37 A–C leaf symptoms in the field. D–F leaf spot samples. *Cladosporium sphaerospermum* (CBS 102045) was used as the outgroup taxon. The best scoring RAxML tree with a final likelihood value of -6579.450688 was presented. The matrix had 293 distinct alignment patterns, with 4.16% of undetermined characters or gaps. Estimated base frequencies were as follows: A = 0.224955, C = 0.297835, G = 0.240548, T = 0.236662; substitution rates AC = 2.713837, AG = 5.914225, AT = 2.658810, CG = 1.741064, CT = 8.493258, GT = 1.000000; gamma distribution shape parameter α = 0.651559. ML bootstrap support values $\geq 50\%$ (BT) and Bayesian posterior probabilities ≥ 0.95 (BYPP) are shown near the nodes. The scale bar indicates 0.06 changes per site. Isolates from the current study are in red and type specimens are in bold.

4.3 Discussion

Grapevine trunk diseases are a huge threat to the sustainable development of the viticulture and viniculture industries, resulting in reduced yields and limited vineyard lifespans (Úrbez-Torres et al., 2020). At the same time, multiple fungal taxa have been recognized to be associated with a specific disease, and field symptoms are complex due to the mixed infection of different pathogens (Patanita et al., 2022). Roles of potential pathogens, effects of endophyte and saprobes, and their interactions among the fungal communities remain unclear. In this study, a total of 40 species belonging to 21 genera in 10 families were identified based on multi-locus phylogenetic analyses and morphological observations. Among them, 22 were first reports on grapevine in China and 12 species were first recorded on grapevine in the world. The top three taxa, *Diaporthe* (19.6%), *Cylindrocarpon*-like fungi (19.1%) and Botryosphaeriaceae (18.6%) accounted for more than half of the total isolates, which are well-established as pathogens causing grapevine trunk disease.

Diaporthe is an important fungal pathogen of grapevine trunk disease around the world, and extensive research has been done on the disease; *Diaporthe dieback*. In China, *Diaporthe eres* was proved to be the most commonly isolated species in both

studies in 2015 and 2019 (Dissanayake et al., 2015a; Manawasinghe et al., 2019). Thus, the result from the present study also accepts this conclusion. Black foot disease is a devastating grapevine trunk disease caused by *Cylindrocarpon*-like fungi, which are common in nurseries and young plantations worldwide (Lawrence et al., 2019). In this study, six *Cylindrocarpon*-like fungal species, belonging to *Dactylonectria*, *Ilyonectria* and *Cylindrocladiella* were identified. Ye et al. (2021a) reported *D. alcacerensis*, *D. torresensis*, *D. macrodidyma* for the first time in China, and *D. novozelandica* has been recently proven to be grapevine pathogens (Tan et al., 2022). *Ilyonectria liriodendri* and *Cylindrocladiella viticola* are common pathogens in many countries, however they have never been reported in China from grapevine previously.

Botryosphaeriaceae encompasses diverse members of pathogens and are regarded as plant opportunistic fungal pathogens (Phillips et al., 2013; Chethana et al., 2016). These species are important pathogens on grapevine and are associated with a series of diseases including leaf spots, shoot dieback, perennial cankers, vascular discoloration and fruit rots (Úrbez-Torres, 2011). More than 20 species from Botryosphaeriaceae have been reported to cause Botryosphaeria dieback (Gramaje et al., 2018). Most Botryosphaeriaceae species isolated and identified in this study have been proven to cause Botryosphaeria dieback in China (Yan et al., 2013; Jayawardena et al., 2018; Wu et al., 2021). *Phaeobotryon rhois* which belongs to Botryosphaeriaceae, has not reported for causing diseases on grapevine. However, this species has been reported to cause branch wilt of *Ulmus pumila* L. and *Rubus crataegifolius* Bge in China (Liu et al., 2020; Zhu et al., 2020).

In addition, two *Phaeoacremonium iranianum* isolates were identified in this study. *Phaeoacremonium* has been reported worldwide for its association with Esca disease, which has become a major concern in all grape-growing countries during the past decades (Hofstetter et al., 2012). However, *Phaeoacremonium iranianum* has not been reported from grapevine in China before. Therefore, based on our collection, this species might be also Esca pathogen which required further confirmation with pathogenicity tests. Pestalotiopsis-like fungi can also cause grapevine trunk disease showing wedge-shaped cankers and bleached canes with slitting (Jayawardena et al., 2015), while species in the current study (*P. kenyana*, *P. rhodomyrtus* and *P. adusta*) have not been reported from grapevine in the world yet.

In addition to the grapevine trunk diseases, several species isolated from this study are associated with grapevines causing different diseases. *Coniella* and *Colletotrichum* are commonly known as grape-fruit pathogens. *Coniella vitis* first reported in 2017 as a novel species causing white rot in China (Chethana et al., 2017). *Colletotrichum* species, including *C. nymphaeae* and *C. viniferum* reported in this study, were reported to cause anthracnose with symptoms of fruit ripe rot and twig dieback (Yan et al., 2015; Liu et al., 2016). *Pestalotiopsis*-like species were also reported to cause fruit rot (Jayawardena et al., 2015). This may prove that the grapevine pathogens not only exist in the main tissues, but also infect other tissues. The roles of these pathogenic taxa on the trunk and root need to be further explored.

Fusarium-like genera comprise many taxa with economic importance, acting as pathogens, saprophytes or endophytes, as well as secondary pathogens (Leslie & Summerell, 2006; Crous et al., 2021). In 1995, *Fusarium oxysporum* was isolated from the roots of declining grapevine in Australia (Highet & Nair, 1995). Recent studies have also identified *Fusarium* species in grapevine nurseries and vineyards. Several *Fusarium* species have been reported as pathogens on grapevines, indicating that *Fusarium* can transfer to being weak or latent pathogens in grapevines from endophytic phases under favourable conditions (Úrbez-Torres et al., 2020). In this study, nine *Fusarium*-like species were identified, belonging to *Fusarium*, *Neocosmospora* and *Bisifusarium*. Except for *F. oxysporum*, other species have not been reported on grapevines in China (Jayawardena et al., 2018). However, the exact life mode and pathogenicity mechanisms of these isolates need to be further explored.

According to the above results, these isolated fungal taxa may have different effects on the grapevine. Grapevine wood is a highly competitive habitat, with the simultaneous presence of plant pathogens and beneficial, potentially protective fungi (Kraus et al., 2019). Pathogenic fungi can change the biotrophic mode from pathogenic to saprotrophic, and become active again once the conditions become favourable, being the primary source of inoculant in a vineyard (Jayawardena et al., 2018). On the other hand, the effect of endophytes on plant disease can be antagonistic, and fungal endophytes diversity can influence the severity of plant diseases (Busby et al., 2016). Thus, the roles of saprotroph, endophyte, and pathogen need to be clarified by pathogenicity tests, and interactions between different communities need to be explored.

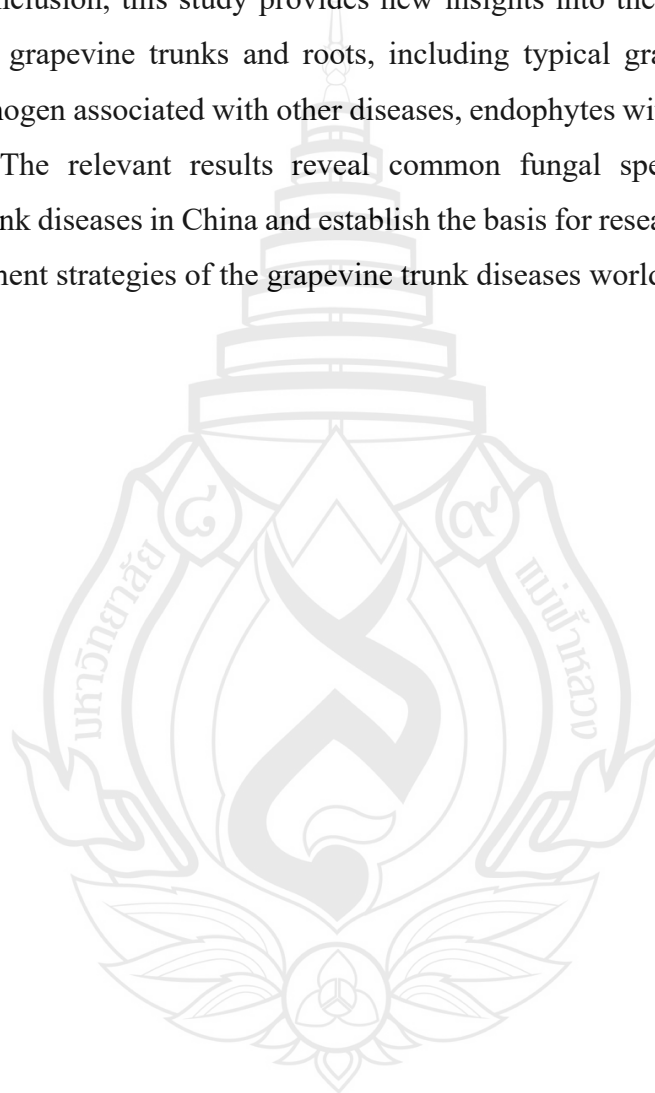

Rather than focus on one of the grapevine trunk diseases, our study conducted an extensive survey on the diverse fungi that covered the main grapevine trunk disease symptoms in China in recent years. This results not only reported new records on the grapevine but also expanded the isolation source of some species compared to previous studies in China (Yan et al., 2013; Ye et al., 2021a, 2021b). For example, *Botryosphaeria dothidea*, *Dactylonectria novozelandica*, *D. macrodidyma*, *Lasiodiplodia pseudotheobromae* and *Neofusicoccum parvum* were first recorded in Yunnan Province; *Alternaria alternata*, *Cladosporium tenuissimum*, *Colletotrichum nymphaeae*, *C. viniferum* and *Diaporthe unshiuensis* were first reported in Fujian Province; *Dactylonectria alcacerensis* and *D. macrodidyma* were first recorded in Beijing; *Dactylonectria alcacerensis* and *L. pseudotheobromae* were first recorded in Hebei Province; and *D. torresensis* was first recorded in Ningxia Province. This may be because of the increase of investigated regions, the transfer of fungi between hosts, as well as the transportation of seedlings carrying pathogens (Manawasinghe et al., 2018). In addition to the parts of sampling and collection site, their distribution, diversity and proportion of fungal taxa may be influenced by climate, environment, and management practices (Mondello et al., 2018). The previous research on the geographical distribution of Botryosphaeriaceae species causing grapevine dieback in China showed that *L. theobromae* was isolated primarily from subtropical monsoon climate regions of China, *Diplodia seriata* isolated primarily from temperate monsoon climate regions, *Neofusicoccum parvum* primarily isolated from central and south China, and *Botryosphaeria dothidea* was isolated from north to south throughout China (Yan et al., 2013). Our results also support these conclusions. Furthermore, these infections may occur through the wounds made during the grapevine planting, or the propagation process, including pruning, retraining, trimming, and de-suckering (Gramaje et al., 2018; Berlanas et al., 2020). To determine the occurrence dynamics of the fungi associated with grapevine trunk disease throughout China, the field of investigation should further enlarge, and more samples should be collected.

The grapevine trunk diseases in fields are usually a mix of different disease types caused by various pathogens rather than a single one. Due to the complexity of the disease and the lack of the most effective chemical products, the management of grapevine trunk diseases is difficult (Gramaje et al., 2018). For pathogens inhabiting vascular tissues, chemical sprays and dips used for controlling surface pathogens could

hardly penetrate dormant grapevine cuttings sufficiently (Waite & May, 2005). It is well-accepted that grapevine trunk diseases should be managed by an integrated disease management strategy, including biological control (Gramaje et al., 2018). *Trichoderma* species are capable of efficient utilization of neighbouring substrates, as well as competitive aggression by secreting antibiotic metabolites and enzymes. With their antagonistic ability, some species have successfully been used in the commercial biological control of fungal pathogens (Schuster & Schmoll, 2010; Lopes et al., 2012). The control efficiency of *Trichoderma* on fungi associated with grapevine trunk disease was demonstrated in the field and nurseries (Kraus et al., 2019). For example, *T. atroviride* and *T. harzianum* applied to the control of Esca caused by *Phaeoconiella chlamydospora* and *Phaeoacremonium* species in nurseries (Pertot et al., 2016; Marco & Osti, 2007), and *T. harzianum* was applied to prevent infection of *Eutypa lata* on grapevine pruning wounds (John et al., 2005). In the current study, three *Trichoderma* species were identified. *Trichoderma virens* is one of the most common biological control agents (BCAs). It has excellent control compared to other fungicides against *Pythium ultimum* infecting cotton and *Rhizoctonia solani* infecting tobacco (Benítez et al., 2004) and was observed to have mediate resistance in tomatoes against Fusarium wilt (Jogaiah et al., 2018). *Trichoderma asperellum* also showed inhibitory activities against *R. solani* on maize and rice, *Sclerotium oryzae* on rice, *A. alternata* on apple, as well as *C. musae* and *F. oxysporum* causing banana fruit rot (Adebesin et al., 2009, Hariharan et al., 2022). Galarza et al. (2015) have assessed the antagonistic activities of *Trichoderma* species against the phytopathogenic fungi from Ecuador and Japan. They have found *T. virens* and *T. asperellum* showing strong inhibitory activities against some *Fusarium*, *Moniliophthora* and *Rosellinia* species (Galarza et al., 2015). *Trichoderma guizhouense* showed a significant effect on root rot of *Vigna unguiculata* caused by *R. solani* (Wang & Zhuang, 2019). *Trichoderma guizhouense* isolates from Italy were evaluated for their potential activity as BCAs in vitro against the canker-causing fungi *Diplodia seriata*, *Eutypa lata* and *Neofusicoccum parvum* (Úrbez-Torres et al., 2020). Interestingly, the isolation results showed that *Cylindrocarpon*-like fungi were sometimes isolated simultaneously with *Trichoderma* isolates. The three *Trichoderma* species in this study, namely *Trichoderma guizhouense*, *T. virens* and *T. asperellum*, may also have the promising ability to become as biocontrol agents for

grapevine trunk diseases. According to the former study by Munkvold and Marois (1993), *Fusarium* and *Cladosporium* showing the antagonistic effect on grapevine trunk disease pathogens. However, antagonistic activities and biocontrol potential of *Alternaria*, *Cladosporium* and *Fusarium* species reported in this study need to be further studied.

In conclusion, this study provides new insights into the diversity of fungi on symptomatic grapevine trunks and roots, including typical grapevine trunk disease agents, a pathogen associated with other diseases, endophytes with biocontrol potential and others. The relevant results reveal common fungal species associated with grapevine trunk diseases in China and establish the basis for research on the occurrence and management strategies of the grapevine trunk diseases worldwide.

CHAPTER 5

IDENTIFICATION ON FUNGAL SPECIES ASSOCIATED WITH BLUEBERRY DISEASE

5.1 A Review of Blueberry Fungal Diseases

5.1.1 The Occurrence of Blueberry Fungal Diseases

Fungal diseases are main threat on blueberry from growing period to shelf life, which cause considerable production and economic losses worldwide (Malarczyk et al., 2019). According to the infected organ and symptoms, fungal diseases are mainly divided into four types including fruit rot, stem blight, leaf spot and root rot, and there are also some minor diseases such as powdery mildew and sooty blotch (Polashock, 2017). Compared with the main fruit crops, the cultivation history of blueberry is relatively short (Janick, 2005). Most researches on blueberry diseases were concentrated in the past two decades, and especially a large number of pathogens were reported in the recent five years. The range of blueberry pathogens is extensive, despite many studies have been conducted on blueberry diseases, many fungal pathogens affecting blueberries may still be undiscovered, and the knowledge on blueberry diseases is still building up.

5.1.2 Blueberry Fruit Rot

Blueberry fruits are perishable as they are susceptible to mechanical damage and infectious diseases for their delicate cell walls, proximity to moist soil, and exposure to rainfall (Malarczyk et al., 2019; Duan et al., 2022). Fruit rot diseases caused by fungi, especially *Botrytis* fruit rot and anthracnose fruit rot, significantly influence the yield and fruit quality pre- and post-harvest (Neugebauer et al., 2024). *Botrytis cinerea* is the predominant causal agent of *Botrytis* fruit rot, causing blights of flowers, leaves, twigs and decay of fruits, also known as grey mould (Rivera et al., 2013; Bell et al., 2021). Alongside *B. cinerea*, *B. pseudocinerea* and *B. californica* have also been reported to cause grey mould on blueberries (Saito et al., 2014; Li et al., 2023). Anthracnose fruit rot is caused by *Colletotrichum* spp., mainly *C. acutatum*, *C. gloeosporioides* and *C. fioriniae* (Wharton et

al., 2008; Eaton et al., 2021). These pathogens can infect blueberries from flowering to harvest and can also be present latent infection and show symptoms in postharvest period. Diseased fruits show sunken lesions with pink or salmon conidial masses (Bell et al., 2021). Anthracnose fruit rot has been reported to cause 10–20% yield loss, and the loss caused by *Botrytis* fruit rot can reach 30%–40% (Polashock et al., 2017). Another fruit rot, caused by *Alternaria* spp., also named Alternaria fruit rot, commonly occurs as an important post-harvest disease during transport and storage, characterized by sunken lesions with white to olivaceous mycelium (Neugebauer et al., 2024; Bell et al., 2021). In addition, *Monilinia vaccinii-corymbosi* and *Exobasidium maculosum* infect young fruits in the early season, causing mummy fruit and fruit spots, respectively (Ingram et al., 2019; Alvarez Osorio et al., 2022). And there are also minor blueberry fruit diseases without specific names, such as the fruit rots caused by *Diaporthe vaccinii*, *Pestalotia vaccinii*, *Phyllosticta vaccinii* and some yeast species (Neugebauer et al., 2024). Although diseases caused by specific pathogens have different names, a single plant can be infected by multiple pathogens. Since most fruit diseases lead to rotting fruit, they are collectively referred to as fruit rot disease (Neugebauer et al., 2024; Polashock et al., 2017). However, the use of specific names, like *Botrytis* fruit rot, Alternaria fruit rot, or anthracnose rot, helps in identifying the most effective management strategies against each particular fungal pathogen.

5.1.3 Blueberry Leaf Spot

Blueberry leaf diseases showed different symptom types including leaf spot, leaf blight, leaf rust, anthracnose and powdery mildew (Lai et al., 2022; Phillips et al., 2022). Typical leaf spot present round to irregular lesions with dark purple to brown border on leaf surface, when visible bright yellow-orange pustules of spores produced on the underside of leaves, the symptoms named leaf rust, while leaf blight refers to the shrivel, curl, or fall off of the leaves (Lai et al., 2022; Phillips et al., 2022). And anthracnose and powdery mildew refer in particular to leaf diseases caused by *Colletotrichum* and *Erysiphe* species respectively (Xu et al., 2013; Bradshaw et al., 2025). As the most common leaf disease type caused by various pathogens, leaf spot is emphasized in this study. Septoria leaf spot was reported on highbush blueberry in USA in the early stage, caused by *Septoria albopunctata* (Alfieri, 1991). The disease was not only causing premature defoliation, but also reductions in photosynthesis of leaves (Roloff et al., 2004). Subsequently the dynamics of Septoria leaf spot was studied on

rabbiteye blueberry, which showed that the occurrence of the disease started between late April and mid-June, and the severity increased until late September (Ojiambo et al., 2007). *Alternaria alternata* (= *Alternaria tenuissima*) was also reported to cause blueberry leaf spot in Argentina and South Korea (Wright et al., 2004; Kwon et al., 2014). In addition, *Calonectria*, *Diaporthe*, *Nigrospora*, *Sphaerulina* and *Exobasidium* were also once recorded (Wright et al., 2008; Ingram et al., 2019; Ali et al., 2021; Chen et al., 2023; Lai et al., 2023). In China, *Pestalotiopsis* species were more frequently reported on blueberry leaves, including *Neopestalotiopsis clavispora*, *Pestalotiopsis adusta*, *P. chamaeropsis*, *P. photinae* and *P. trachicarpicola* (Luan et al., 2007; Chen et al., 2010; Zheng et al., 2023). The occurrence of leaf spot is often present as compound symptom together with fruit and stem disease, such as leaf spot, twig blight, and fruit rot of blueberry caused by *Alternaria alternata* (= *Alternaria tenuissima*) (Wright et al., 2004), leaf and fruit spot caused by *Exobasidium maculosum* (Ingram et al., 2019), as well as leaf spot and stem blight on blueberry caused by *Calonectria pseudoreteauidii* (Chen et al., 2023).

5.1.4 Blueberry Stem Blight

Stem blight is one of the most common and severe disease among blueberry diseases, resulting in reduced production and economic losses (Martino et al., 2024). In New Zealand, the disease incidence has reached 18%, causing \$500,000 in annual losses (Sammonds et al., 2009); in Chile, the incidence rate ranges from 15 to 45% (Espinoza et al., 2009). As the top producer of blueberries, China also suffered 10% to 25% of crop damage from the disease (Zhao et al., 2019). Stem blight is caused by several fungal pathogens that infect plants through wounds or natural openings, leading to vascular damage, wood discoloration, and even the death of the plant (Martino et al., 2024; Ru et al., 2023). As a general term, stem blight is also known as stem canker or dieback. Typical symptoms of the disease are reddish-brown to grey-brown lesions on stems, shoots, or twigs (Hilário et al., 2021; Zhao et al., 2022; Zheng et al., 2023). *Pestalotiopsis*-like (*Pestalotiopsis* and *Neopestalotiopsis*) species, *Diaporthe* and many genera of Botryosphaeriaceae (*Botryosphaeria*, *Neofusicoccum* and *Lasiodiplodia*) are major causal agents of stem blight worldwide (Ru et al., 2023; Hilário et al., 2021; Zheng et al., 2023). Canker or dieback usually refer to diseases caused by Botryosphaeriaceae species on other hosts such as grapevine (Úrbez-Torres et al., 2009;

Yan et al., 2013), while on blueberry, though Botryosphaeriaceae species were also reported to cause dieback and cankers (Castillo et al., 2013; Tennakoon et al., 2018), these disease names are not strictly related to specific pathogens, but also sometimes related to *Diaporthe* and *Pestalotiopsis* species (Elfar et al., 2013; Zheng et al., 2023; Blagojević et al., 2024). These may because of the symptoms caused by different pathogens are difficult to distinguish. Additionally, some disease names are more emphasize on specific parts like twig blight or branch blight (Wright et al., 2014; Chen et al., 2016). For stem blight is the most commonly used name, here these names are collectively called stem blight. In addition to above fungal groups, *Calonectria*, *Colletotrichum*, *Nigrospora* and *Sphaerulina* species have been reported to cause stem blight on blueberries (Wright et al., 2008; Xu et al., 2013; Ali et al., 2021; Chen et al., 2023). The diversity of pathogens contributing to stem blight highlights its nature as a disease complex, making it difficult to distinguish based on field symptoms.

5.1.5 Blueberry Root Rot

Blueberry root rots are caused by fungi (Ascomycota and Basidiomycota), and fungus-like organisms (Oomycota). *Phytophthora cinnamomi*, one of the top 10 oomycete pathogens infecting huge number of plant hosts, is an important pathogen causing Phytophthora root rot on blueberry (Kamoun et al., 2015; Huarhua et al., 2018). Records of fungal pathogens are more scattered, including *Calonectria ilicicola* in China (Fei et al., 2018), *Fusarium commune* in China (Li et al., 2023), *Fusarium proliferatum* in Argentina (Pérez et al., 2011), *Fusarium oxysporium* in China (Liu et al., 2014), *Neocosmospora solani* in Argentina (Pérez et al., 2007), *Neopestalotiopsis clavisporea* in China (Xue et al., 2018) and *Armillaria* species in Italy (Prodorutti et al., 2009). Root rots usually present symptoms of leaf chlorosis, dark brown to black rot of the root and stem base, and the withered and died of the whole plant in severe case (Fei et al., 2018; Huarhua et al., 2018; Li et al., 2023). Compared with fruit, stem and leaf diseases, records on blueberry root rots are relatively fewer, while the infection on roots usually cause the symptoms of the whole plants and harder to detected from overground part. With regard to the profound impact of root disease on plant health, and more root pathogens recorded in China than other countries, more attention should be paid on root rot disease.

5.1.6 Common Fungal Pathogens on Blueberry

5.1.6.1 *Neopestalotiopsis* and *Pestalotiopsis* species. Among multiple pathogens, members of *Pestalotiopsis sensu lato* (pestalotioid fungi) are distributed throughout temperate and tropical regions (Maharachchikumbura et al., 2014; Liu et al., 2019). *Pestalotiopsis* and *Neopestalotiopsis* are the main pathogenic genera causing twig blight, stem cankers, and dieback on blueberry plants, as well as leaf diseases (Santos et al., 2022). Many studies documented the presence of pestalotioid fungi associated with blueberries disease in Argentina (leaf spots and branch cankers) (Fernández et al., 2015), Brazil (leaf spot) (Araujo et al., 2023), Chile (canker and twig Dieback) (Espinoza et al., 2008), China (leaf spot, root rot) (Luan et al., 2008; Xue et al., 2018), Czech Republic (stem blight and dieback) (Spetik et al., 2023), Korea (twig dieback) (Lee et al., 2019), Mexico (leaf rust) (Rebollar-Alviter et al., 2011), Peru (stem blight and dieback) (Rodríguez-Gálvez et al., 2020), Portugal (twig blight and dieback) (Santos et al., 2022), Spain (canker and twig dieback) (Borrero et al., 2018), Turkey (leaf spot and branch blight) (Dil et al., 2013) and Uruguay (twig and branch dieback) (González et al., 2012). And the most-reported pestalotioid species on blueberry plants are *Neopestalotiopsis clavispora* (syn. *Pestalotiopsis clavispora*) (González et al., 2012; Borrero et al., 2018; Xue et al., 2018; Lee et al., 2019), *N. rosae* (Rodríguez-Gálvez et al., 2020; Santos et al., 2022), *Pestalotiopsis microspora* (Jin et al., 2021) and *P. neglecta* (Espinoza et al., 2008). In China, *P. clavispora* has been reported to cause leaf spot, twig blight, stem canker and root rot (Luan et al., 2008; Chen et al., 2016; Xue et al., 2018; Zheng et al., 2023). In addition, *P. trachicarpicola*, *P. chamaeropsis*, *P. adusta* and *P. photiniae* were also reported to cause stem canker and leaf spot (Chen et al., 2010; Zheng et al., 2023).

5.1.6.2 Botryosphaeriaceae species. Botryosphaeriaceae is also a dominant pathogen causing stem disease in blueberries (Scarlett et al., 2019). A large number of *Botryosphaeriaceae* species have been found to associate with stem blight and cankers of blueberry plants in Australia (stem blight and dieback) (Scarlett et al., 2019), Chile (stem canker and dieback) (Espinoza et al., 2009), China (stem blight) (Xu et al., 2015), Korea (bark dieback) (Choi, 2011), Mexico (stem blight and dieback) (Boyzo-Marin et al., 2016), New Zealand (dieback) (Tennakoon et al., 2018), Peru (stem blight and dieback) (Rodríguez-Gálvez et al., 2020), Portugal (stem blight and dieback) (Hilário

et al., 2020), Spain (stem canker and dieback) (Castillo et al., 2013) and the United States (stem blight) (Wright & Harmon, 2010). *Botryosphaeria* stem blight is the most destructive disease affecting blueberry production worldwide, caused by more than 20 species in the genera *Botryosphaeria*, *Neofusicoccum*, *Lasiodiplodia* and *Macrophomina* (González et al., 2012; Zhao et al., 2019; Wang et al., 2021; Ru et al., 2023). To date, *Botryosphaeria dothidea*, *Neofusicoccum parvum*, *N. vaccinii*, *N. vitifusiforme*, *Lasiodiplodia clavisporea*, *L. fujianensis*, *L. henanica*, *L. nanpingensis*, *L. paraphysoides*, *L. pseudotheobromae*, *L. theobromae*, *L. vaccinii*, *L. chinensis* and *Macrophomina vaccinii* have been reported to cause infections of blueberries in China (Kong et al., 2010; Yu et al., 2012b; Xu et al., 2015; Zhao et al., 2019, 2022; Wang et al., 2021).

5.1.6.3 *Diaporthe* species. *Diaporthe* is also a causal agent frequently reported, causing stem blight (Hilário et al., 2021), postharvest rot (Yu et al., 2018) and leaf spot (Lai et al., 2023). *Diaporthe eres* (= *Diaporthe vaccinii*) which is considered a concern to blueberry production worldwide, has been widely reported in South America, North America, Europe and Asia (Hilário et al., 2021). In addition, *Diaporthe ambigua*, *D. amygdali*, *D. crousii*, *D. foeniculina*, *D. hybrida*, *D. leucospermi*, *D. passiflorae* (= *D. malorum*) and *D. rudis* (= *D. australafricana*) were reported to cause stem diseases in Chile, Poland, Portugal, Serbia (Elfar et al., 2013; Hilário et al., 2021; Michalecka et al., 2023; Blagojević et al., 2024). Hilário et al. (2022) sequenced and analysed the genomes of *D. amygdali* (CAA958) and *D. eres* (CBS 160.32), identifying cellular transporters associated with the transport of toxins, ions, sugars, and effectors, as well as genes linked to pathogenicity in genomes of the both species. In China, leaf spot disease caused by *Diaporthe phoenicicola* (Lai et al., 2023), postharvest rot by *Diaporthe nobilis* (Yu et al., 2018) and stem canker by *Diaporthe sojiae* (Li et al., 2023d) have been reported.

5.1.6.4 *Fusarium*. Researches on *Fusarium* from blueberry is relatively limited. The genus usually as the causal agent of wilt, root rot and fruit rot disease. *Neocosmospora solani* and *F. proliferatum* were reported to cause root rot of blueberry in Argentina (Pérez et al., 2007; Pérez et al., 2011), *F. acuminatum* was reported to cause stem blight in Argentina and postharvest fruit rot in China respectively (Wright et al., 2014; Wang et al., 2016). *Fusarium* wilt caused by *F. oxysporum* was reported in

China and Chile (Liu et al., 2014; Moya-Elizondo et al., 2019). Additionally, *Fusarium commune* was reported to cause blueberry root rot in China (Li et al., 2023).

5.1.6.5 Other pathogens. In addition to the above dominant pathogens, *Botrytis*, *Colletotrichum* and *Alternaria* species are also common pathogens (Wright et al., 2004; Kwon et al., 2011; Liu et al., 2020). And some other genera such as *Calonectria*, *Nigrospora*, *Septoria*, *Truncatella* and *Thekopsora*, were also found to be associated with blueberry diseases (Roloff et al., 2004; Espinoza et al., 2008; Rebollar-Alviter et al., 2011; Zhang et al., 2019b; Chen et al., 2023b).

5.1.6.6 Blueberry pathogens in China. Currently forty-seven species belonging to ten family have been reported to associated with blueberry disease in China. The information of the species including blueberry species, associated diseases, locality, and identification methods are provided in table 5.1. The summary shows that stem blight (canker/dieback) is most common reported in China. *Botryosphaeria dothidea* is the most widely distributed (eight provinces), followed by *Neofusicoccum parvum* (six provinces) and *Neopestalotiopsis clavispora* (five provinces). The occurrence of other species are only in one to three regions. In addition, though the phylogenetic analyses have become widespread, fungal identification in many studies still based on morphology and single gene alignment. Therefore, to get more knowledge on disease diagnosis and management, more researches are necessary on the identification and distribution of fungi associated with blueberry diseases.

Table 5.1 Recorded fungal species associated with blueberry disease in China

Family	Species	Host species	Associated disease	Locality	Identification method	Reference
Apiosporaceae	<i>Nigrospora oryzae</i>	<i>Vaccinium corymbosum</i>	Leaf spot	Shanghai	Morphology+ sequence BLAST	Zhang et al. (2019)
Botryosphaeriaceae	<i>Botryosphaeria dolichospermatii</i>	<i>Vaccinium uliginosum</i>	Stem canker	Fujian	Morphology + multi-locus phylogeny	Chu et al. (2021)
	<i>Botryosphaeria dothidea</i>	<i>Vaccinium corymbosum</i>	Stem blight and dieback	Fujian, Jiangsu, Liaoning, Shandong, Shanghai, Sichuan, Yunnan, Zhejiang	Morphology+ sequence BLAST/ multi-locus phylogeny	Yu et al. (2012), Xu et al. (2015)
	<i>Botryosphaeria fujianensis</i>	<i>Vaccinium uliginosum</i>	Stem canker	Fujian	Morphology + multi-locus phylogeny	Chu et al. (2021)

5.2 Characterization of Fungal Pathogens Causing Blueberry Fruit Rot Disease in China

5.2.1 Disease Symptoms and Fungal Isolation

Fruit rot samples were collected from blueberry orchards in Fujian and Guizhou Provinces, China. Symptoms appeared during the green fruit stage, showing the gradual progression of decay. Diseased fruits dry-up, shrink, rot, and sometimes exude fluid. Stems turned brown, dry-out, and develop mould (Figure 5.1). Disease incidence was 2%-3%.

Sixteen isolates were generated from six samples, and were identified as seven species based on morphological characters and phylogenetic analyses. They include *Botryosphaeria dothidea*, *Botrytis cinerea*, *Cladosporium guizhouense*, *Colletotrichum fioriniae*, *Diaporthe anacardii*, *Fusarium annulatum* and *Neopestalotiopsis surinamensis*.

Figure 5.1 Symptoms of the blueberry fruit rot

Figure 5.1 A–B Field symptoms of blueberry fruit rot. C Died twigs with shrunken fruits. D Shrivelled fruit with mould.

5.2.2 Taxonomy

Botryosphaeria dothidea (Moug.: Fr.) Ces. & De Not., Comm. Soc. crittog. Ital. 1 (fasc. 4): 212 (1863).

Index Fungorum: IF 183247; Facesoffungi Number: FoF 03512.

Classification: Botryosphaeriaceae, Botryosphaeriales, Dothideomycetes, Ascomycota, Fungi (Hyde et al., 2024).

Pathogenic on fruits of *Vaccinium* sp. **Sexual morph:** Not observed. **Asexual morph:** *Conidiomata* produced on the PNA, pycnidial, solitary, globose, dark brown. *Conidiophores* 7–20 × 2–5 μm (\bar{x} = 13.3 × 3.1 μm, n = 30), hyaline, smooth, cylindrical, or reduced to conidiogenous cells. *Conidiogenous cells* holoblastic, hyaline, subcylindrical. *Conidia* 19–31 × 5–9 μm (\bar{x} = 25.2 × 6.9 μm, n = 50), hyaline, smooth with granular contents, aseptate, narrowly fusiform, with subtruncate to bluntly rounded base, apex sub-obtuse.

Culture characteristics – Colonies on PDA reaching 76 mm diam. after three days at 25°C, initially white, aerial mycelia fluffy with an irregular margin, subsequently becoming grey, reverse black, mycelial mat moderately dense.

Material examined – CHINA, Fujian Province, isolated from diseased fruit of *Vaccinium* spp., May 2023, Y. Y. Zhou and X. H. Li (dry cultures JZBH310277, JZBH310278), living cultures JZB310277, JZB310278.

Notes – As the type species of *Botryosphaeria* and one of the most common species in the order Botryosphaeriales, the taxonomy of *Botryosphaeria dothidea* has undergone large changes (Marsberg et al., 2017). The development of molecular technology resolved the problem of species concept among numerous morphologically similar specimens (Slippers et al., 2004). Subsequently, some taxa were separated from *B. dothidea*, and some were reduced to synonymy with *B. dothidea* (Zhang et al., 2021; Marsberg et al., 2017). In this study, we follow the taxonomy of Zhang et al. (2021). In the phylogenetic analyses, the two isolates (JZB310277 and JZB310278) clustered within the clade of *Botryosphaeria dothidea* with 66% ML bootstrap and 0.97 Bayesian probabilities (Figure 5.2), and they showed similar morphology (Figure 5.3) compared with the type description of *B. dothidea* (CBS 115476) (Phillips et al., 2013). *Botryosphaeria dothidea* is globally distributed, with a wide range of woody hosts, causing canker or dieback of twigs, branches and stems, fruit rots, and even death of

the plant in severe cases (Marsberg et al., 2017). In China, fruit rots caused by *Botryosphaeria dothidea* have been observed on kiwifruit, plum, pomegranate, as well as blueberry (Zhang et al., 2016; Gu et al., 2020; Wang et al., 2021; Yuan et al., 2024).

Figure 5.2 Phylogenetic tree generated by maximum likelihood (ML) analysis of combined ITS, *tef 1- α* , *β -tub* sequence data of *Botryosphaeria* species

Figure 5.2 The tree is rooted with *Cophinforma eucalypti* (CBS 134651). The matrix has 201 distinct alignment patterns, with 15.63% being undetermined characters or gaps. Estimated base frequencies are as follows: A = 0.211405; C = 0.307730; G = 0.252687; T = 0.228178. Substitution rates: AC = 0.564762; AG = 3.067476; AT = 0.831148; CG = 0.764470; CT = 5.328705; GT = 1.000000. Gamma distribution shape parameter: $\alpha = 1.261108$. ML bootstrap support values $\geq 60\%$ and Bayesian posterior probabilities (BYPP) ≥ 0.90 are given near the nodes. The scale bar indicates 0.009 changes. Arrows represents the value at nodes. The ex-type strains are in bold, and newly generated sequences are in red.

Figure 5.3 Morphological characters of *Botryosphaeria dothidea* (JZB310278)

Figure 5.3 A Upper view of the colony on PDA after three days; B Reverse view of the colony on PDA after three days; C Upper view of the colony on PDA after seven days; D Reverse view of the colony on PDA after seven days; E Colony sporulating on PNA; F, G Conidiogenous cells and developing conidia; H Conidia. Scale bars: F, H = 20 μ m; G = 10 μ m.

Botrytis cinerea Pers., Syn. meth. fung. (Göttingen) 2: 690 (1801).

Index Fungorum: IF 217312; Facesoffungi Number: FoF 03832.

Classification: Sclerotiniaceae, Helotiales, Leotiomyces, Ascomycota, Fungi (Hyde et al., 2024).

Pathogenic on fruits of *Vaccinium* sp. For morphology, see the taxonomy description by Fillinger and Elad (2016) (description and illustration) and Bell et al. (2021) (record on blueberry fruit).

Material examined – CHINA, Guizhou Province, isolated from diseased fruits of *Vaccinium* spp., May 2023, Y. Y. Zhou and X. H. Li (dry cultures JZBH350048–JZBH350051), living cultures JZB350048–JZB350051.

Notes – Phylogenetic analyses of the combined multi-locus dataset shows that our four isolates (JZB350048–JZB350051) clustered together with the ex-type strain of

B. cinerea (MUCL87), with 90% ML bootstrap values and 1.00 Bayesian probabilities (Figure 5.4), and the isolates are morphologically identical to *Botrytis cinerea* (Figure 5.5). *Botrytis cinerea* is a cosmopolitan pathogen, infecting more than 200 plant species, including fruits, vegetables, and ornamental plants, leading to significant losses (Dean et al., 2012). The species has been reported as a major pathogen causing pre- and postharvest fruit rot on blueberry (Neugebauer et al., 2024).

Figure 5.4 Phylogenetic tree generated by maximum likelihood (ML) analysis of combined *rpb2*, *gapdh*, *hsp60* sequence data of *Botrytis* species

Figure 5.4 The tree is rooted with *Sclerotinia sclerotiorum* (484). The matrix had 700 distinct alignment patterns, with 2.36% of characters or gaps undetermined. Estimated base frequencies were as follows: A = 0.271469, C = 0.237560, G = 0.235321, T = 0.255650; substitution rates AC = 1.400180, AG = 4.179758, AT = 1.216816, CG = 0.677408, CT = 10.830994, GT = 1.000000. Gamma distribution shape parameter $\alpha = 0.770821$. ML bootstrap support values $\geq 60\%$ and Bayesian posterior probabilities (BYPP) ≥ 0.90 are given near the nodes. The scale bar indicates 0.02 changes. The ex-type strains are in bold and newly generated sequences are in red.

Cladosporium guizhouense S.Y. Wang, Yong Wang bis & Yan Li, MycoKeys 91: 160 (2021).

Index Fungorum: IF 842407; Facesoffungi Number: FoF 15881.

Classification: Cladosporiaceae, Cladosporiales, Dothideomycetes, Ascomycota, Fungi (Hyde et al., 2024).

Pathogenic on fruits of *Vaccinium* sp. **Sexual morph:** Not observed. **Asexual morph:** Hyphomycetous. *Mycelium* 1.7–4.2 μm wide, abundant, immersed, composed of septate, branched, pale olivaceous brown hyphae, smooth to slightly verruculose, with thin walls. *Conidiophores* 48–112 \times 3–4 μm (\bar{x} = 88.2 \times 3.2 μm ; n = 10), micro- to macronematous, solitary, formed laterally or terminally from hyphae, erect, branched, pale to medium olivaceous brown. *Conidia* 3–8 \times 2–4 μm (\bar{x} = 5.4 \times 2.8 μm ; n = 30), forming unbranched or branched acropetal chains, aseptate, pale olivaceous, smooth, thin-walled, ovoid, ellipsoid or subcylindrical. *Secondary ramoconidia* 6–20 \times 3–5 μm (\bar{x} = 12 \times 3.5 μm ; n = 30), aseptate, pale olivaceous, smooth, thin-walled, ellipsoid to subcylindrical.

Culture characteristics – Colonies on PDA reaching 39 mm diam. after seven days at 25°C, flat, aerial mycelium velvety to floccose, olivaceous, reverse dark grey with white margin.

Material examined – CHINA, Guizhou Province, isolated from diseased fruits of *Vaccinium* spp., May 2023, Y. Y. Zhou and X. H. Li (dry cultures JZBH390091, JZBH390092), living cultures JZB390091, JZB390092.

Notes – Two *Cladosporium* isolates generated in the present study (JZB390091, JZB390092) formed a sister clade with *C. guizhouense* strains with 100% ML bootstrap values and 1.0 Bayesian probabilities (Figure 5.6). Morphological characters of the two isolates (Figure 5.7) are similar to the original description of *C. guizhouense* (Wang et al., 2022). *Cladosporium guizhouense* was introduced as a saprobe on fallen leaves of *Eucommia ulmoides* by Wang et al. (2022) in Guizhou Province, China, and subsequently isolated from *citrus reticulata* (Yang et al., 2023). The species was also reported as a mycoparasite on rust fungi (Silva et al., 2023; Pereira et al., 2024). This is the first report of *C. guizhouense* on blueberry (*Vaccinium* spp.).

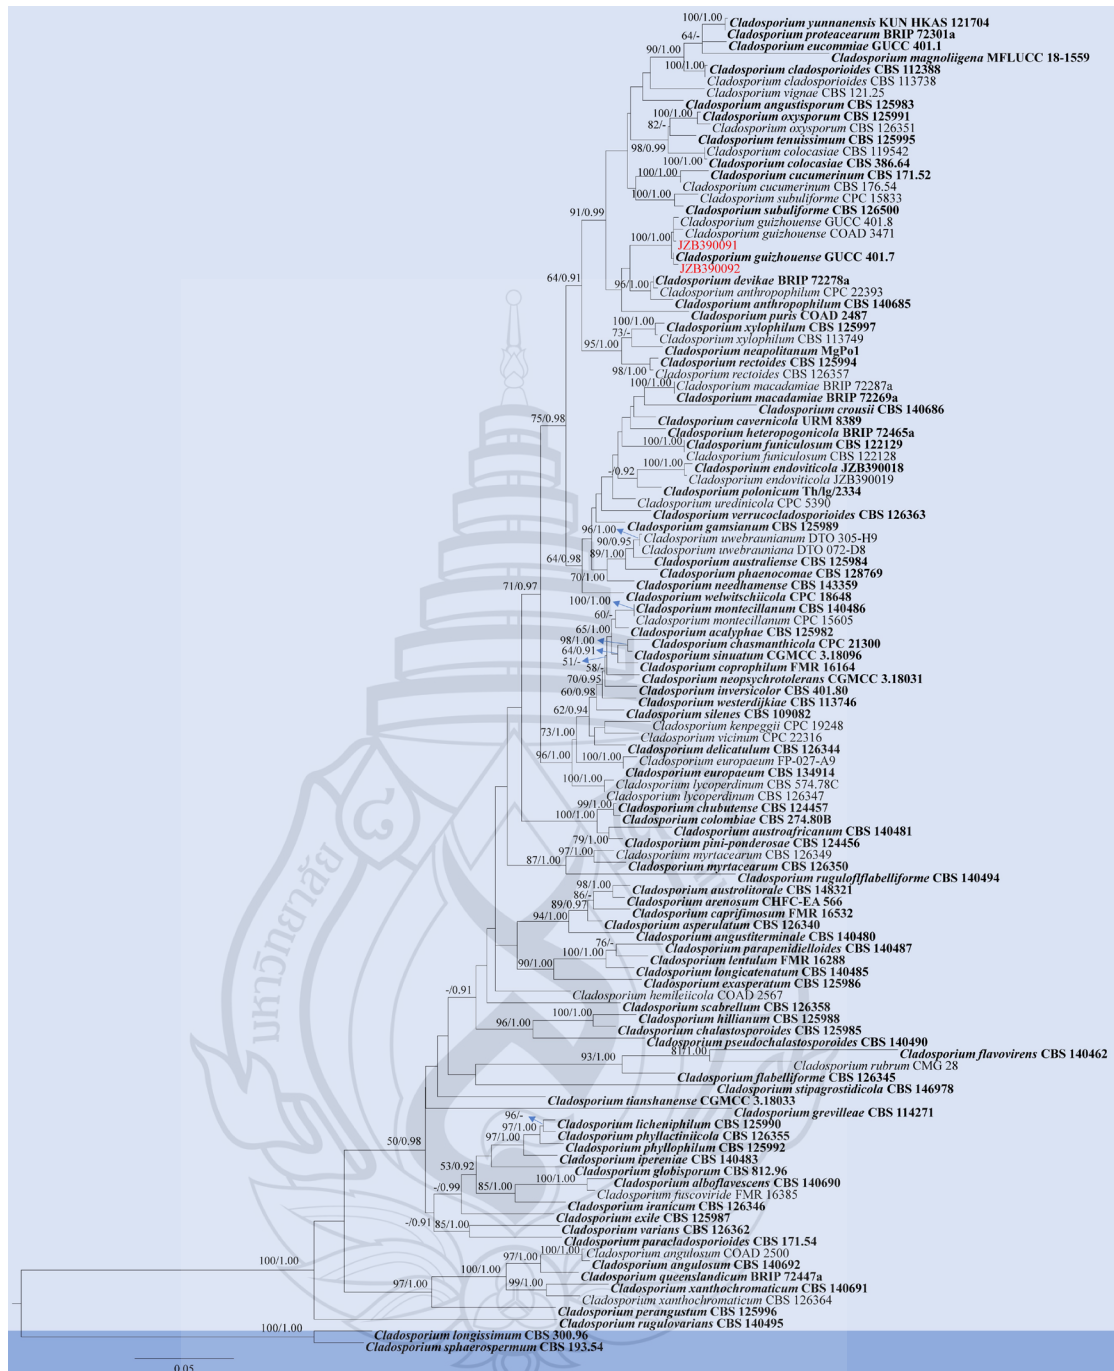

Figure 5.6 Phylogenetic tree generated by maximum likelihood (ML) analysis of combined ITS, *act*, *tef 1- α* sequence data of *Cladosporium cladosporioides* species complex

Figure 5.6 The tree is rooted with *Cladosporium longissimum* (CBS 300.96) and *Cladosporium sphaerospermum* (CBS 193.54). The matrix had 480 distinct alignment patterns, with 6.11% of undetermined characters or gaps. Estimated base frequencies

were as follows: A = 0.228323, C = 0.293145, G = 0.245258, T = 0.233274; substitution rates AC = 2.384560, AG = 5.066431, AT = 2.461368, CG = 1.411300, CT = 8.523585, GT = 1.000000; gamma distribution shape parameter $\alpha = 0.714986$. ML bootstrap support values $\geq 50\%$ and Bayesian posterior probabilities (BYPP) ≥ 0.90 are given near the nodes. The scale bar indicates 0.05 changes. Arrows represents the value at nodes. The ex-type strains are in bold and newly generated sequences are in red.

Figure 5.7 Morphological characters of *Cladosporium guizhouense* (JZB390091)

Figure 5.7 A Upper view of the colony on PDA after seven days; B Reverse view of the colony on PDA after seven days; C Mycelia and conidiophore on SNA; D–F Conidiophore, secondary ramoconidia and conidia. Scale bars: D–F = 20 μm .

Colletotrichum fioriniae (Moug.: Fr.) (Marcelino & Gouli) Pennycook, Mycotaxon 132(1): 150 (2017) [2016].

Index Fungorum: IF 553097; Facesoffungi Number: FoF 02891.

Classification: Glomerellaceae, Glomerellales, Sordariomycetes, Ascomycota, Fungi (Hyde et al., 2024).

Pathogenic on fruits of *Vaccinium* sp. For morphology, see description by Damm et al. (2012) (description and illustration) and Bell et al. (2022) (record on blueberry fruit).

Material examined – CHINA, Guizhou Province, isolated from diseased fruits of *Vaccinium* spp., May 2023, Y. Y. Zhou and X. H. Li (dry cultures JZBH330439, JZBH330440), living cultures JZB330439, JZB330440.

Notes – The two isolates obtained in this study (JZB330439, JZB330440) clustered with *C. fioriniae* strains in the phylogenetic analysis (100% ML bootstrap and 1.00 BYPP) (Figure 5.8), and share similar morphological characters (Figure 5.9) with the type description of *C. fioriniae* (Damm et al., 2012). *Colletotrichum fioriniae* is widely distributed around the world, especially in temperate regions (Talhinhas & Baroncelli, 2021). The species is one of the most common *Colletotrichum* species in China with more than 30 hosts and has been isolated from anthracnose fruit rot of litchi, peaches, and pears (Fu et al., 2019; Ling et al., 2021; Liu et al., 2022; Tan et al., 2022). This is the first report of *C. fioriniae* causing fruit rot on blueberry (*Vaccinium* spp.) in China.

Figure 5.8 Phylogenetic tree generated by maximum likelihood (ML) analysis of combined ITS, *gapdh*, *chs*, *act*, *β -tub* sequence data of *Colletotrichum acutatum* species complex

Figure 5.8 The tree is rooted with *Colletotrichum orchidophilum* (CBS 632.80). The matrix had 542 distinct alignment patterns, with 3.67% of undetermined characters or gaps. Estimated base frequencies were as follows: A = 0.231239, C = 0.296836, G = 0.244083, T = 0.227842; substitution rates AC = 1.611674, AG = 4.644984, AT = 1.380603, CG = 0.638683, CT = 7.444475, GT = 1.000000; gamma distribution shape parameter α = 0.920840. ML bootstrap support values $\geq 50\%$ and Bayesian posterior probabilities (BYPP) ≥ 0.90 are given near the nodes. The scale bar indicates 0.02

changes. Arrows represents the value at nodes. The ex-type strains are in bold and newly generated sequences are in red.

Figure 5.9 Morphological characters of *Colletotrichum fioriniae* (JZB330439)

Figure 5.9 A Upper view of the colony on PDA after seven days. B Reverse view of the colony on PDA after seven days. C Conidiomata on PNA. D–G Conidiophores. H Conidia. I–L Appressoria. Scale bars: D, E, H = 20 µm; F, G, I–L = 10 µm.

Diaporthe anacardii (Early & Punith.) R.R. Gomes, Glienke & Crous, *Persoonia* 31: 15 (2013).

Index Fungorum: IF 802923; Facesoffungi Number: FoF 16978.

Classification: Diaporthaceae, Diaporthales, Sordariomycetes, Ascomycota, Fungi (Hyde et al., 2024).

Pathogenic on fruits of *Vaccinium* sp. **Sexual morph:** Not observed. **Asexual morph:** *Conidiomata* pycnidial, globose, black. *Conidiophores* 10–21.5 × 1–2 µm (\bar{x} = 15.1 × 1.4 µm; n = 30), densely aggregated, branched, straight to slightly sinuous, smooth, hyaline, cylindrical, slightly tapering towards the apex. *Alpha conidia* 6–9 × 2–3 µm (\bar{x} = 7.6 × 2.8 µm; n = 50), straight, aseptate, bi-guttulate or multi-guttulate,

hyaline, fusoid to ellipsoid, slightly tapering towards both ends. Beta conidia not observed.

Culture characteristics – Colonies on PDA reaching 78 mm diam. after five days at 25°C, white with moderate, felted aerial mycelium, reverse yellowish to brownish at the centre.

Material examined – CHINA, Fujian Province, isolated from diseased fruits of *Vaccinium* spp., May 2023, Y. Y. Zhou and X. H. Li (dry cultures JZBH320308), living cultures JZB320308.

Notes – For the taxonomic treatment of *Diaporthe*, we followed the latest classification proposed by Norphanphoun et al. (2022) and Dissanayake et al. (2024). The phylogenetic analysis showed that our isolate JZB320308 clustered within the clade of *Diaporthe anacardii*, sister to CGMCC 3.18286 and LC4419 (= *D. velutina*) (Figure 5.10), and the morphology characters of JZB320308 (Figure 5.11) conformed to the description of *D. anacardii* (Gao et al., 2017). *Diaporthe anacardii* was introduced from *Anacardium occidentale* in Africa (as *Phomopsis anacardii*) (Early & Punithalingam, 1972), and was epitypified by Gomes et al. (2013). According to the new classification system, *D. acutispora*, *D. nebulae*, *D. phillipsii*, *D. portugallica* and *D. velutina* are reduced to synonymy with *D. anacardii* (Dissanayake et al., 2024). Among them *D. phillipsii* was originally introduced as a pathogen associated with blueberry twig blight and dieback in Portugal (Hilário et al., 2020). This is the first report of *D. anacardii* causing fruit rot on blueberry in China.

Figure 5.10 Phylogenetic tree generated by maximum likelihood (ML) analysis of combined ITS, *tef 1- α* , *β -tub*, *cal*, *his* sequence data of Section Foeniculina of *Diaporthe* species

Figure 5.10 The tree is rooted with *Diaporthe citri* (CBS 135422). The matrix had 1121 distinct alignment patterns, with 25.45% of undetermined characters or gaps. Estimated base frequencies were as follows: A = 0.214637, C = 0.324631, G =

0.237836, T = 0.222897; substitution rates AC = 1.200371, AG = 3.247133, AT = 1.039432, CG = 0.794522, CT = 4.498676, GT = 1.000000; gamma distribution shape parameter $\alpha = 0.912183$. ML bootstrap support values $\geq 50\%$ and Bayesian posterior probabilities (BYPP) ≥ 0.90 are given near the nodes. The scale bar indicates 0.03 changes. Arrows represents the value at nodes. The ex-type strains are in bold and newly generated sequences are in red.

Fusarium annulatum Bugnic., Rev. gén. Bot. 59: 13 (1952).

Index Fungorum: IF 297536; Facesoffungi Number: FoF 16723.

Classification: Nectriaceae, Hypocreales, Sordariomycetes, Ascomycota, Fungi (Hyde et al., 2024).

Pathogenic on fruits of *Vaccinium* sp. **Sexual morph:** Not observed. **Asexual morph:** *Conidiophores* on CLA produced laterally on aerial mycelium and substrate mycelium, straight or flexuous, simple or more commonly sympodially to irregularly branched, or reduced to conidiogenous cells borne laterally on hyphae; *Conidiogenous cells* mono- and polyphialidic, subulate to cylindrical; *Microconidia* 5–10 × 2–3.5 μm (\bar{x} = 7.0 × 2.6 μm; n = 50), formed on aerial conidiophores, hyaline, obovoid to ellipsoidal, smooth- and thin-walled, aseptate, forming a false head on phialides. *Macroconidia* 21.5–55.5 × 4–5.5 μm (\bar{x} = 40.9 × 4.5 μm; n = 30), sparse, straight to slightly curved, tapering toward the basal part; apical cell blunt; basal cell barely notched, 2–4-septate, hyaline, thin- and smooth-walled. *Chlamydospores* absent.

Culture characteristics – Colonies on PDA reaching 75 mm diam. after six days at 25°C, flat, light purple to orange with abundant aerial mycelia.

Material examined – CHINA, Fujian Province, isolated from diseased fruits of *Vaccinium* spp., May 2023, Y. Y. Zhou and X. H. Li (dry cultures JZBH3110489, JZBH3110490), living cultures JZB3110489, JZB3110490.

Notes – According to the phylogenetic analyses, two isolates in this study (JZB3110489, JZB3110490) clustered within the clade of *Fusarium annulatum* (Figure 5.12). *Fusarium annulatum* was introduced by Bugnicourt (1952) from *Oryza sativa*, and was reported to infect multiple plant hosts under the name *F. proliferatum* (Seifert et al., 2003). Yilmaz et al. (2021) fixed the typification of *F. proliferatum* to a distinct phylogenetic clade, and provided an emended description of *F. annulatum*. *Fusarium annulatum* showed phylogenetic diversity and differentiation in morphology. According to the original description of the type strain (CBS 258.54) by Bugnicourt (1952), sporodochial conidia of *F. annulatum* are strongly curved and almost ring-shaped, and Nelson et al. (1983) regraded *F. annulatum* as *F. proliferatum* with strongly curved, sporodochial conidia (macroconidia), while Yilmaz et al. (2021) found that most *F. annulatum* isolates only produce straight, sporodochial conidia. Our study confirmed that macroconidia are straight to slightly curved (Figure 5.13). *Fusarium*

annulatum was reported to cause blight on *Bletilla striata*, maize, and *Rosa roxburghii* rot disease in China (Xu et al., 2022; Zhang et al., 2023; Zhang et al., 2024). This is the first report of *F. annulatum* causing fruit rot on blueberry (*Vaccinium* spp.).

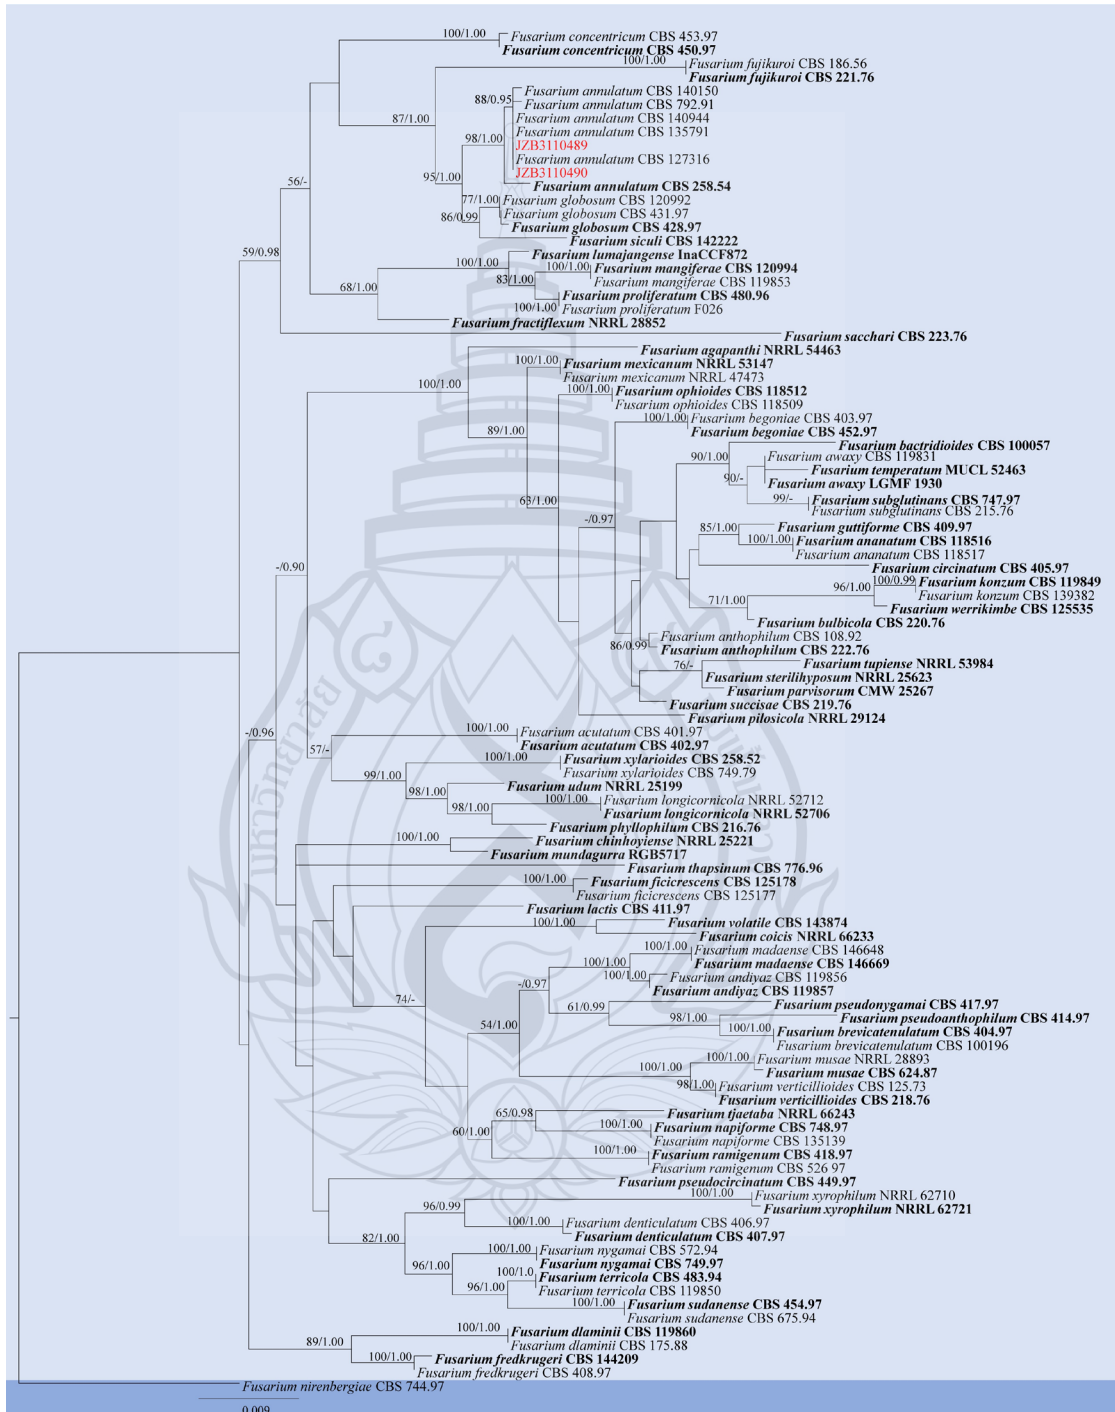

Figure 5.12 Phylogenetic tree generated by maximum likelihood (ML) analysis of combined *tef 1-α* and *rpb2* sequence data of *Fusarium* species

Figure 5.12 The tree is rooted with *Fusarium nirenbergiae* (CBS 744.97). The matrix had 421 distinct alignment patterns, with 3.70% of undetermined characters or gaps. Estimated base frequencies were as follows: A = 0.263854, C = 0.251445, G = 0.251382, T = 0.233319; substitution rates AC = 1.435916, AG = 6.155181, AT = 1.375277, CG = 0.854277, CT = 13.787190, GT = 1.000000; gamma distribution shape parameter $\alpha = 0.814503$. ML bootstrap support values $\geq 50\%$ and Bayesian posterior probabilities (BYPP) ≥ 0.90 are given near the nodes. The scale bar indicates 0.009 changes. The ex-type strains are in bold and newly generated sequences are in red.

Figure 5.13 A Upper view of the colony on PDA after six days. B Reverse view of the colony on PDA after six days. C Sporodochia formed on CLA. D, E Aerial conidiophores. F Microconidia. G–L Macroconidia. Scale bars: D–F = 10 μm ; G–L = 20 μm .

Neopestalotiopsis surinamensis Maharachch., K.D. Hyde & Crous, in Maharachchikumbura, Hyde, Groenewald, Xu & Crous, Stud. Mycol. 79: 149 (2014).

Index Fungorum: IF 809781; Facesoffungi Number: FoF 16979.

Classification: Sporocadaceae, Amphisphaeriales, Sordariomycetes, Ascomycota, Fungi (Hyde et al., 2024).

Pathogenic on fruits of *Vaccinium* sp. **Sexual morph:** Not observed. **Asexual morph:** *Conidiomata* subglobose to globose, scattered or gregarious, semi-immersed or erumpent, exuding globose, black conidial masses. *Conidiophores* indistinct, often reduced to conidiogenous cells. *Conidiogenous cells* discrete, ampulliform, flask-shaped to subcylindrical, smooth-walled, hyaline. *Conidia* 20–27 × 7–9.5 μm (\bar{x} = 23.0 × 8.1 μm; n = 30), fusoid, ellipsoid to subcylindrical, straight to slightly curved, 4-septate; basal cell 3.5–5 μm long, obconic with a truncate base, hyaline, rugose and thin-walled; three median cells 14–18.5 μm (\bar{x} = 15.7 μm; n = 30) long, doliiform, wall rugose, versicolored, brown to pale brown, septa darker than the rest of the cell, second cell from the base 5–6 μm long, pale brown to brown; third cell 4.5–6 μm long, brown; fourth cell 4.5–6 μm long, brown; apical cell 3–4 μm long, hyaline, conical to subcylindrical, thin- and smooth-walled; apical appendages 2–4, 12.5–28.5 μm (\bar{x} = 20.2 μm; n = 30) long, tubular, arising from the apical crest, unbranched, filiform; basal appendage 3.5–7.5 μm (\bar{x} = 5.0 μm; n = 30) long, single, tubular, unbranched, centric.

Culture characteristics – Colonies on PDA reaching 79 mm diam. after five days at 25°C, raised with lobate margin, white, reverse pale yellow, aerial mycelia dense, flocculent.

Material examined – CHINA, Fujian Province, isolated from diseased fruits of *Vaccinium* spp., May 2023, Y. Y. Zhou and X. H. Li (dry cultures JZBH340093–JZBH340095), living cultures JZB340093–JZB340095.

Notes – In the phylogenetic tree of *Neopestalotiopsis*, three isolates from this study (JZB340093–JZB340095) grouped with the ex-type strain of *Neopestalotiopsis surinamensis* (CBS 450.74) and another strain (MFTU06-3) (Figure 5.14). Morphologically, isolates in this study (Figure 5.15) were similar to the original description of *N. surinamensis* by Maharachchikumbura et al. (2014). However, minor dimensional differences were observed in the size of basal cell and apical cell, which may be attributed to host differences. *Neopestalotiopsis surinamensis* was introduced

from soil under *Elaeis guineensis* in Suriname and living leaves of *Protea eximia* in Zimbabwe (Maharachchikumbura et al., 2014), and was reported as a pathogen causing guava scab (Solarte et al., 2018). This is the first report of *Neopestalotiopsis surinamensis* causing blueberry fruit rot.

Figure 5.14 Phylogenetic tree generated by maximum likelihood (ML) analysis of combined ITS, *tef1-α* and *tub2* sequence data of *Neopestalotiopsis* species

Figure 5.14 The tree is rooted with *Pestalotiopsis spathulate* (CBS 356.86) and *Pestalotiopsis diversiseta* (MFLUCC 12-0287). The matrix had 606 distinct alignment patterns, with 13.33% of undetermined characters or gaps. Estimated base frequencies were as follows: A = 0.234657, C = 0.273247, G = 0.214726, T = 0.277370; substitution rates AC = 1.150331, AG = 1.150331, AT = 1.150331, CG = 0.850459, CT = 4.628454, GT = 1.000000; gamma distribution shape parameter $\alpha = 0.898468$. ML bootstrap support values $\geq 50\%$ and Bayesian posterior probabilities (BYPP) ≥ 0.90 are given near the nodes. The scale bar indicates 0.009 changes. Arrows represents the value at nodes. The ex-type strains are in bold and newly generated sequences are in red.

Figure 5.15 Morphological characters of *Neopestalotiopsis surinamensis* (JZB340093)

5.2.3 Pathogenicity Test

Among the 16 isolates obtained from blueberry fruit rot, one representative isolate from each genus was selected for pathogenicity assay using spore suspensions. These include *Botryosphaeria dothidea* (JZB310278), *Botrytis cinerea* (JZB350048), *Cladosporium guizhouense* (JZB390091), *Colletotrichum fioriniae* (JZB330439), *Diaporthe anacardii* (JZB320308), *Fusarium annulatum* (JZB3110489) and *Neopestalotiopsis surinamensis* (JZB340093). All experimental isolates showed virulence on blueberry fruits with different symptoms (Figure 5.16). Fruits inoculated with *F. annulatum* formed white mycelia at the inoculation site; fruits inoculated with *D. anacardii* showed soft rot with a fluid exuded from the inoculation site; fruits inoculated with *B. cinerea* showed a rot surrounded by grey white mycelia; fruits inoculated with *C. fioriniae* secreted orange conidial mass; fruits inoculated with *B. dothidea* shrivelled and produced black globose conidiomata; fruits inoculated with *C. guizhouense* produced lesion with olive-green colony, and fruits inoculated with *N. surinamensis* produced a lesion shrivelled and formed white mycelia and black conidiomata. No symptoms were induced in the control fruits inoculated with sterile water. Fungal pathogens were re-isolated from lesions and confirmed by morphology and ITS sequence to prove Koch's postulates.

Figure 5.16 Detached fruit pathogenicity test for the fungal isolates on blueberry fruits five days post inoculation

Figure 5.16 A Control (sterilized water); B *Fusarium annulatum* (JZB3110489); C *Diaporthe anacardii* (JZB320308); D *Botrytis cinerea* (JZB350048); E, I *Colletotrichum fioriniae* (JZB330439); F J *Botryosphaeria dothidea* (JZB310278); G K *Cladosporium guizhouense* (JZB390091); H, L *Neopestalotiopsis surinamensis* (JZB340093).

5.2.4 Summary

In this section, seven fungal pathogens causing blueberry fruit rot disease in Guizhou and Fujian Provinces were identified and characterized, and their pathogenicity on fruits were confirmed. *Cladosporium guizhouense*, *Fusarium annulatum*, and *Neopestalotiopsis surinamensis* were reported for the first time on blueberry. The study demonstrated that fruit rot disease results from a mixed infection of multiple pathogens; and expanded the understanding of causal agents of blueberry fruit rot during the growth stage, highlighting their potential as latent pathogens that contribute to post-harvest losses. Relevant results provide a reference for the etiological research and disease management in blueberry fruit diseases.

5.3 Characterization of Micro-Fungi Associated with Blueberry Leaf, Stem and Root Diseases in China

5.3.1 Investigation, Sampling and Fungal Isolation

During the investigation of blueberry diseases in Fujian, Guizhou, Heilongjiang, Jilin and Liaoning from March to September in 2023, leaf spot, stem blight and root rot were found to be the most common diseases, with incidence rate from 1%–5%, and more than one symptom could appear on one plant (Figure 5.17):

1. Leaf spot: appear as pinpoint spots on leaves, enlarge to brown to purple lesion, and gradually expand and coalesce, until the wither and defoliation of leaves;
2. Stem blight: blight, dieback and canker were observed on twig, shoot and stem, here they are collectively called stem blight. Affected stems showed irregular, reddish-brown lesions that extended to both sides of the stem, and the tip became shrivelled and withered;

3. Root rot: main root or fibrous root showed brown and necrosis, plants affected by diseases usually short and poor-developed, with yellow leaves.

For typical symptoms, 94 diseased samples (25 leaf samples, 54 stem samples and 15 root samples) were collected, and 429 fungal isolates were generated by tissue isolation.

5.3.2 Composition and Information of Fungal Taxa

Isolates were preliminarily identified as forty genera, which are mostly belong to the class Sordariomycetes and Dothideomycetes. *Neopestalotiopsis* (15%), *Alternaria* (11%), *Fusarium* (11%), *Pestalotiopsis* (11%), *Botryosphaeria* (10%) are top five genera with highest proportion, accounting more than half of total isolate numbers (Figure 5.18).

A total of ninety species was identified by morphological characters and phylogenetic analysis, while there are additional twenty-one undetermined species, which need more morphological or molecular data. Species information was listed in Table 5.1, including classification (unidentified species were expressed by sp.), isolate

number, isolation source, isolation region and the records on blueberry. According to the results, seventy-eight species were newly recorded on blueberry worldwide (new host records), four species were first reported on blueberry in China (new host-geography association records), and three new species were proposed. The classification of fungi in this study followed Hyde et al. (2024).

Figure 5.18 The proportion of isolate numbers divided by genera

Table 5.2 Species list in this study

Genus	Species	Number of isolates	Isolation source	Isolation region	Records on blueberry
1 Ascomycota					
1.1 Dothideomycetes

5.3.3 Prevalence of Fungal Genera Associated with Blueberry Diseases

5.3.3.1 Distribution of fungal genera by isolation source.

The 121 isolates from leaf sample belong to twenty-two genera, with *Pestalotiopsis* (22% isolation rate of the total isolates), *Neopestalotiopsis* (15%), *Diaporthe* (12%) and *Alternaria* (12%) as the dominant genera (Figure 5.19a). The 249 isolates from stem sample belong to thirty-two genera, with *Neopestalotiopsis* (17%), *Alternaria* (13%), *Botryosphaeria* (12%) and *Fusarium* (10%) as the dominant genera (Figure 5.19b). The 59 isolates from root sample belong to seventeen genera, with *Fusarium* (29%), *Neocosmospora* (8%), *Neopestalotiopsis* (8%), *Diaporthe* (7%) and *Dactylonectria* (7%) as the dominant genera (Figure 5.19c).

Among the forty genera generates, nine genera distributed simultaneously in the three parts: *Neopestalotiopsis*, *Alternaria*, *Fusarium*, *Botryosphaeria*, *Diaporthe*, *Cladosporium*, *Epicoccum*, *Neocosmospora*, *Clonostachys*. Four genera were only found in leaves: *Botrytis*, *Neodeightonia*, *Phyllosticta* and *Annulohyphoxylon*. Ten genera, including *Bipolaris*, *Pseudofusicoccum* and *Curvularia* were only found in stems. *Dactylonectria*, *Trichoderma*, *Ilyonectria* and *Calonectria* were only found in roots (Figure 5.20).

Note a leaf. b stem. c root.

Figure 5.19 Isolation rate (%) of genera from blueberry organs

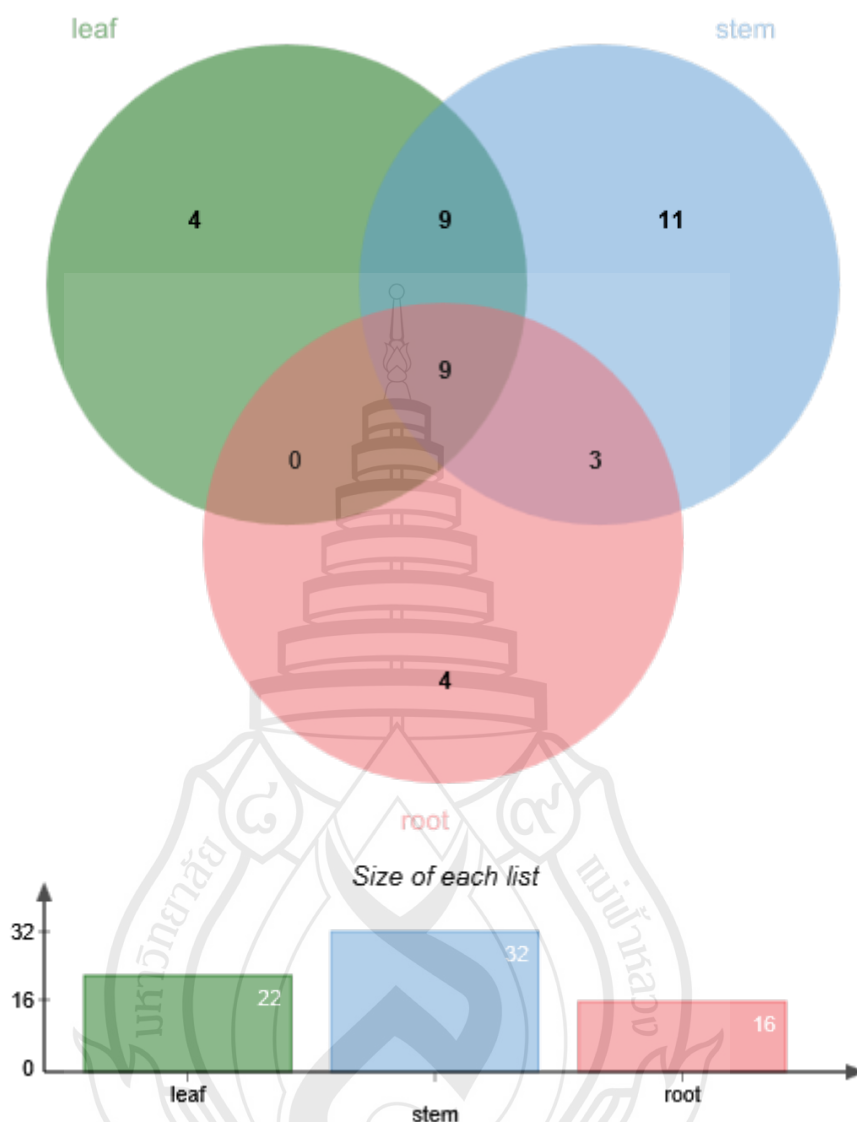

Figure 5.20 Distribution of fungal genera in blueberry leaf, stem and root

5.3.3.2 Distribution of fungal genera by collecting region.

In Fujian Province, 121 isolates belong to twenty-two genera were generated, with *Pestalotiopsis* (19%), *Neopestalotiopsis* (18%) and *Diaporthe* (13%) as dominant genera. In Guizhou Province, 59 isolates belong to fifteen genera were generated, with *Pestalotiopsis* (22%), *Fusarium* (12%) and *Diaporthe* (10%) as dominant genera. In Heilongjiang Province, 55 isolates belong to nine genera were generated, with *Alternaria* (27%), *Botryosphaeria* (27%) and *Bipolaris* (13%) as dominant genera. In Jilin Province, 101 isolates belong to nineteen genera were

generated, with *Neopestalotiopsis* (20%), *Alternaria* (18%) and *Diaporthe* (12%) as dominant genera.

Neopestalotiopsis, *Fusarium* and *Botryosphaeria* species were the only three genera distributed in all the five regions. *Alternaria* was distributed in four regions except for Fujian Province, while *Coniella* was only found in Fujian. *Pestalotiopsis* and *Diaporthe* species were distributed in four regions except for Heilongjiang Province, while *Bipolaris* was only found in Heilongjiang (Figure 5.21).

Figure 5.21 Distribution of fungal genera in five provinces of China

5.3.4 Characterization of Pestalotioid Fungi Associated with Blueberry Leaf, Stem and Root Diseases

Neopestalotiopsis Maharachch., K.D. Hyde & Crous, in Maharachchikumbura, Hyde, Groenewald, Xu & Crous, Stud. Mycol. 79: 135 (2014)

Classification: Sporocadaceae, Amphisphaeriales, Sordariomycetes, Ascomycota, Fungi (Hyde et al., 2024).

Notes: *Neopestalotiopsis*, typified by *Neopestalotiopsis protearum*, was proposed by Maharachchikumbura et al. (2014), distinguished from *Pestalotiopsis* by versicolourous median cells with indistinct conidiophores. As previously a portion of *Pestalotiopsis*, the genus *Neopestalotiopsis* is also common phytopathogens, endophytes and saprobes, and more and more new species have been observed in the recent years (Razaghi et al., 2024). Currently there are 119 epithets in the Index Fungorum (2024). Razaghi et al. (2024) made a re-evaluation on *Neopestalotiopsis*, and found that it is difficult to distinguish the two genera only based on morphology, because there are some morphological exceptions compared with previous recognized criterion, such as some members of *Neopestalotiopsis* and *Pestalotiopsis* produce more than 5-celled typical conidia, and distinct conidiophores and concolourous conidia were observed in many *Neopestalotiopsis* species. In addition, most *Pestalotiopsis*-like species are phylogenetically ambiguous, thus the type specimens of known species, especially species introduced by host-association, need to be further studied (Razaghi et al., 2024).

In this study, phylogenetic tree of *Neopestalotiopsis* was constructed based on ITS, *tef 1- α* and *β -tub* sequence data using ML and Bayesian analyses, with *Pseudopestalotiopsis cocos*, *Pseudopestalotiopsis indica* and *Pseudopestalotiopsis theae* as outgroups (Figure 5.22). New isolates from this study clustered into fourteen clades close to *Neo. castanopsidis*, *Neo. chrysea*, *Neo. collariata*, *Neo. concentrica*, *Neo. haikouensis*, *Neo. jiangxiensis*, *Neo. keteleeriae*, *Neo. iberica*, *Neo. photiniae*, *Neo. protearum*, *Neo. rosae*, *Neo. scalabiensis*, *Neo. subepidermalis* and *Neo. vacciniicola*. Combined with morphological characters, sixty-five new collections were identified as fourteen species, including ten new host records.

Figure 5.22 Phylogenetic tree generated from maximum likelihood (ML) analysis based on combined ITS, *tef 1-a* and β -*tub* sequence data of *Neopestalotiopsis*

Figure 5.22 (continued)

Figure 5.22 The alignment comprises 1,785 characters with gaps. The tree is rooted with *Pseudopestalotiopsis cocos* (CBS 272.29), *Pseudopestalotiopsis indica* (CBS 459.78) and *Pseudopestalotiopsis theae* (MFLUCC 12-0055 and SC011). The tree topology of the ML analysis was similar to the Bayesian analysis. The best-scoring RAxML tree with a final likelihood value of -11172.378134 is presented. The matrix had 811 distinct alignment patterns, with 9.43% of undetermined characters or gaps. Estimated base frequencies were as follows: A = 0.234198, C = 0.273929, G = 0.213469, T = 0.278403; substitution rates AC = 0.945317, AG = 3.489706, AT = 1.239642, CG = 0.684809, CT = 4.846636, GT = 1.000000; gamma distribution shape parameter α = 0.640278. ML bootstrap support values $\geq 50\%$ and Bayesian posterior probabilities (BYPP) ≥ 0.90 are given near the nodes. The scale bar indicates the number of nucleotide changes per site. Ex-type strains are indicated in bold and newly generated sequences are indicated in red.

Neopestalotiopsis castanopsis P. Razaghi, F. Liu & L. Cai, in Razaghi, Raza, Han, Ma, Cai, Zhao, Chen, Phurbu & Liu, Stud. Mycol. 109: 214 (2024). Figure 5.23

Associated with stem blight of *Vaccinium corymbosum*. **Sexual morph:** Not observed. **Asexual morph:** *Conidiomata* globose, solitary or gregarious, semi-immersed or immersed, exuding globose, black conidial masses. *Conidiophores* indistinct, often reduced to conidiogenous cells. *Conidiogenous cells* discrete, ampulliform, flask-shaped or obclavate, hyaline, 9–14.5 × 2–5 µm (\bar{x} = 12.9 × 3.2 µm, n = 30). *Conidia* fusoid to ellipsoid, straight to slightly curved, 4-septate, 20–23 × 7–9 µm (\bar{x} = 21.5 × 8 µm, n = 30), L/W ratio = 2.7; basal cell obconic with a truncate base, hyaline, rugose and thin-walled, 3–4 µm long (\bar{x} = 3.2 µm, n = 30); three median cells doliiform, 13–16 µm (\bar{x} = 14.7 µm, n = 30) long, wall rugose, versicoloured, septa darker than the rest of the cell (second cell from the base pale brown, 4–5 µm long; third cell brown, 5–6 µm long; fourth cell brown, 4.5–5.5 µm long); apical cell 3–4.5 µm (\bar{x} = 3.5 µm, n = 30) long, hyaline, conical to subcylindrical, thin- and smooth-walled, with 2–4 tubular apical appendages (mostly 3), arising from the apical crest, unbranched, filiform, flexuous, 17.5–38 µm (\bar{x} = 24.5 µm, n = 30) long; basal appendage single, tubular, unbranched, centric, 4–7.5 µm (\bar{x} = 6.1 µm, n = 30) long.

Culture characteristics – Colonies on PDA reaching 67 mm diam. after four days at 25°C, flat with lobate edge, concentric, white, aerial mycelium sparse, flocculence.

Material examined – China, Fujian Province, Longyan City, from diseased leaves of *Vaccinium corymbosum*, May 2023, X. H. Li and Y. Y. Zhou (dry cultures JZBH340096– JZBH340097), living cultures JZB340096– JZB340097.

Notes – The two new isolates from this study (JZB340096–JZB340097) phylogenetically close to the ex-type of *Neopestalotiopsis castanopsis* (CGMCC 3.23478) with 85% ML bootstrap support and 1.00 Bayesian posterior probabilities. The morphology of the isolates is also similar to the description of the ex-type of *Neo. castanopsis* (Razaghi et al., 2024). The two isolates are identified as *Neo. castanopsis*. *Neopestalotiopsis castanopsis* was introduced from *Castanopsis boisii* in China (Razaghi et al., 2024). This is the first report of *Neo. castanopsis* on blueberry (*Vaccinium* spp.).

Figure 5.23 Morphological characters of *Neopestalotiopsis castanopsidis* (JZB340096)

Figure 5.23 a Colony on PDA after four days; b Colony on PDA after three weeks; c Conidiomata on PDA; d–f Conidiogenous cells; g–j Conidia; Scale bars: c=1000 μm ; d=20 μm ; e–j=10 μm

Neopestalotiopsis chrysea (Maharachch. & K.D. Hyde) Maharachch., K.D. Hyde & Crous, in Maharachchikumbura, Hyde, Groenewald, Xu & Crous, Stud. Mycol. 79: 138 (2014). Figure 5.24

Associated with leaf spot of *Vaccinium corymbosum*.

Sexual morph: Not observed. **Asexual morph:** *Conidiomata* globose, solitary or gregarious, semi-immersed or immersed, exuding globose, black conidial masses. *Conidiophores* indistinct, often reduced to conidiogenous cells. *Conidiogenous cells*

discrete, ampulliform, flask-shaped or obclavate, hyaline, $8.1\text{--}14.5 \times 2.4\text{--}4.5 \mu\text{m}$ ($\bar{x} = 11.0 \times 3.3 \mu\text{m}$, $n = 30$). *Conidia* fusoid to ellipsoid, straight to slightly curved, 4-septate, $19.1\text{--}25.0 \times 6.4\text{--}9.6 \mu\text{m}$ ($\bar{x} = 22.6 \times 8.0 \mu\text{m}$, $n = 50$), L/W ratio = 2.8; basal cell obconic with a truncate base, hyaline, rugose and thin-walled, $3.3\text{--}5.6 \mu\text{m}$ long ($\bar{x} = 4.2 \mu\text{m}$, $n = 20$); three median cells doliiform, $13\text{--}17.4 \mu\text{m}$ ($\bar{x} = 15.2 \mu\text{m}$, $n = 20$) long, wall rugose, versicoloured, septa darker than the rest of the cell (second cell from the base pale brown to brown, $3.7\text{--}5.4 \mu\text{m}$ long; third cell brown, $4.0\text{--}6.2 \mu\text{m}$ long; fourth cell brown, $3.9\text{--}5.5 \mu\text{m}$ long); apical cell $2.7\text{--}4.8 \mu\text{m}$ ($\bar{x} = 3.7 \mu\text{m}$, $n = 20$) long, hyaline, conical to subcylindrical, thin- and smooth-walled, with 2–4 tubular apical appendages (mostly 3), arising from the apical crest, unbranched or branched at one appendage, filiform, flexuous, $11.2\text{--}37.0 \mu\text{m}$ ($\bar{x} = 22.4 \mu\text{m}$, $n = 30$) long; basal appendage single, tubular, unbranched, centric, $3.0\text{--}11.6 \mu\text{m}$ ($\bar{x} = 5.6 \mu\text{m}$, $n = 30$) long.

Culture characteristics – Colonies on PDA reaching 66–68 mm diam. after four days at 25°C, flat with lobate edge, concentric, colony from above white, becoming pale yellow after three weeks; colony from reverse pale yellow in centre, becoming rosy-buff after three weeks.

Material examined – China, Fujian Province, Longyan City, from diseased leaves of *Vaccinium corymbosum*, May 2023, X. H. Li and Y. Y. Zhou (dry cultures JZBH340098–JZBH340105), living cultures JZB340098–JZB340105.

Notes – In the phylogenetic tree of *Neopestalotiopsis*, eight new isolates from this study (JZB340098–JZB340105) clustered with *Neo. chrysea* with 56% ML bootstrap support. Sequences of JZB340098 and JZB340099 have 2 nucleotide differences (tub2: 2/520) from ex-type of *Neo. chrysea* (MFLUCC 12-0261), while sequences of JZB340100–JZB340105 have 3 nucleotide differences (tef1: 1/450; tub2: 2/520) from ex-type of *Neo. chrysea* (MFLUCC 12-0261). Morphology characters of our isolates are similar to *Neo. chrysea* except for smaller L/W ratio of conidia (2.8 vs. 3.7 in *Neo. chrysea*). In spite of this, the evidence is not sufficient to distinguish our isolates from *Neo. chrysea*. Based on phylogeny and morphology, we identified our new collections as *Neo. chrysea*. *Neopestalotiopsis chrysea* was originally introduced as *Pestalotiopsis chrysea* from dead plant material in China (Maharachchikumbura et al., 2012). Subsequently *Pes. chrysea* was transferred to *Neopestalotiopsis* as *Neopestalotiopsis chrysea* (Maharachchikumbura et al., 2014). *Neopestalotiopsis chrysea* has been reported to cause twig blight of rabbit-eye

blueberry (*Vaccinium virgatum*) in Fujian, China (Shi et al., 2017). Here we isolated the species in the same Province, on highbush blueberry (*Vaccinium corymbosum*).

In addition, we also compared the morphology of species adjacent to *Neo. chrysea*, including *Neo. fragariae*, *Neo. elaeagni*, *Neo. asiatica* and *Neo. umbrinospora*. As the comparison shown in table 5.3, their morphological characters are basically similar except for slight differences: the conidiogenous cells of *Neo. fragariae* is narrower, while the dimensions of conidiogenous cells of *Neo. chrysea* and *Neo. umbrinospora* are absent; and the number of apical appendages different among species. However, the differences are not distinct for the dimension ranges of conidiogenous cells, conidia and appendages are highly overlapped. If these species be synonymized need to be further studied.

Figure 5.24 Morphological characters of *Neopestalotiopsis chrysea* (JZB340098)

Figure 5.24 a Colony on PDA after four days; b Colony on PDA after three weeks; c Conidiomata on PDA; d-f Conidiogenous cells; g-j Conidia; Scale bars: c=500µm; d=20 µm; e-j=10 µm

Table 5.3 Comparison of the conidial dimension of *Neopestalotiopsis* species related to this study

Species	Material examined	Conidiogenous cells (μm)	Conidial size (μm)	L/W ratio	Apical Appendages		Basal Appendage (μm)	Reference
					Number	Length (μm)		
<i>Neo. chrysea</i>	JZB340098	8.1–14.5 \times 2.4–4.5	19.1–25.0 \times 6.4–9.6	2.8	2–4 (mostly 3)	11.2–36.8	3.0–11.6	This study
	HMAS042855	-	20–24 \times 5.5–7	3.7	3	22–30	3–6	Maharachchikumbura et al. (2012)
<i>Neo. fragariae</i>	ZHKUCC 22-0113	8–13 \times 1–2	17–26 \times 5–9	3.1	2–4 (mostly 3)	10.4–32.8	3.0–11.5	Prematunga et al. (2022)
<i>Neo. elaeagni</i>	GUCC 21002	8–13 \times 2–3	19–25 \times 4.5–7	-	1–3	13–30	5–7.5	He et al. (2022)

Neopestalotiopsis collariata P. Razaghi, F. Liu & L. Cai, in Razaghi, Raza, Han, Ma, Cai, Zhao, Chen, Phurbu & Liu, Stud. Mycol. 109: 215 (2024). Figure 5.25.

Associated with leaf spot of *Vaccinium corymbosum*. **Sexual morph:** Not observed. **Asexual morph:** *Conidiomata* globose, solitary or gregarious, semi-immersed or immersed, exuding globose, black conidial masses. *Conidiophores* indistinct, often reduced to conidiogenous cells. *Conidiogenous cells* discrete, ampulliform, flask-shaped or obclavate, hyaline, 7.5–12.5 × 2–3 µm (\bar{x} = 9.5 × 2.7 µm, n = 30). *Conidia* fusoid to ellipsoid, straight to slightly curved, 4-septate, 18–24 × 7.5–10 µm (\bar{x} = 21.7 × 8.7 µm, n = 30), L/W ratio = 2.4; basal cell obconic with a truncate base, hyaline, rugose and thin-walled, 3.5–4 µm long (\bar{x} = 4.0 µm, n = 30); three median cells doliform, 15.5–19.5 µm (\bar{x} = 18.0 µm, n = 30) long, wall rugose, versicoloured, septa darker than the rest of the cell (second cell from the base pale brown, 5–6 µm long; third cell brown, 5–7 µm long; fourth cell brown, 5.5–7 µm long); apical cell 3.5–5.5 µm (\bar{x} = 4.7 µm, n = 30) long, hyaline, conical to subcylindrical, thin- and smooth-walled, with 2–4 tubular apical appendages (mostly 3), arising from the apical crest, unbranched, filiform, flexuous, 18.5–30 µm (\bar{x} = 22.6 µm, n = 30) long; basal appendage single, tubular, unbranched, centric, 4.5–5.5 µm (\bar{x} = 5.0 µm, n = 30) long.

Culture characteristics – Colonies on PDA reaching 67 mm diam. after four days at 25°C, flat with lobate edge, concentric, white, aerial mycelium sparse, flocculence.

Material examined – China, Fujian Province, Longyan City, from diseased leaves of *Vaccinium corymbosum*, May 2023, X. H. Li and Y. Y. Zhou (dry cultures JZBH340106–JZBH340107), living cultures JZB340106–JZB340107.

Notes – The two new isolates from this study (JZB340106–JZB340107) phylogenetically close to the ex-type of *Neopestalotiopsis collariata* (CGMCC 3.23493). The morphology of the isolates is also similar to the description of the ex-type of *Neo. collariata* (Razaghi et al., 2024). The two isolates are identified as *Neo. collariata*. *Neo. collariata* was introduced from *Rhododendron* (Ericaceae) and branches of *Diospyros kaki* in Jiangxi Province and Fujian Province in China (Razaghi et al., 2024). This is the first report of *Neo. collariata* on blueberry (*Vaccinium* spp.), which also suggesting the re-emergence of the species from Ericaceae host in Fujian Province, China.

Figure 5.25 Morphological characters of *Neopestalotiopsis collariata* (JZB340106)

Figure 5.25 a Colony on PDA after four days; b Colony on PDA after three weeks; c Conidiomata on PDA; d–f Conidiogenous cells; g–j Conidia; Scale bars: c=1000 μm ; d=20 μm ; e–j=10 μm .

Neopestalotiopsis concentrica C. Peng & C.M. Tian, in Peng, Crous, Jiang, Fan, Liang & Tian, *Persoonia* 49: 227 (2022)

Associated with leaf spot and stem blight of *Vaccinium corymbosum*. For morphological description, see Peng et al. (2022).

Material examined – China, Fujian Province, Longyan City, from leaf spot of *Vaccinium corymbosum*, May 2023, X. H. Li and Y. Y. Zhou (dried cultures JZBH340108–JZBH340109), living cultures JZB340108–JZB340109; *ibid.*, from stem blight of *Vaccinium corymbosum*, May 2023, X. H. Li and Y. Y. Zhou (dried cultures JZBH340110–JZBH340111), living cultures JZB340110–JZB340111.

Notes – In the phylogenetic analysis, four isolates obtained in the current study (JZB340108–JZB340111) clustered with ex-type of *Neopestalotiopsis concentrica* (CFCC 55162). And the morphological characters are similar to the ex-type isolate of *Neo. concentrica* (Peng et al., 2022). *Neopestalotiopsis concentrica* was introduced by Peng et al. (2022) from spines of *Rosa* spp. in China. And Zhang et al. (2024) isolated the species from leaf spots of *Rhapis excelsa*. This is the first report of *Neopestalotiopsis concentrica* on *Vaccinium* spp.

Neopestalotiopsis haikouensis Z.X. Zhang, J.W. Xia & X.G. Zhang, in Zhang, Liu, Liu, Mu, Zhang & Xia, MycoKeys 88: 181 (2022). Figure 5.26, Figure 5.27

Associated with stem blight of *Vaccinium corymbosum*.

Description from JZB340113 (Figure 5.26): **Sexual morph:** Not observed. **Asexual morph:** *Conidiomata* globose, solitary or gregarious, semi-immersed or immersed, exuding globose, black conidial masses. *Conidiophores* indistinct, often reduced to conidiogenous cells. *Conidiogenous cells* discrete, ampulliform, flask-shaped or cylindrical, hyaline, 6.2–17.6 × 2.0–5.2 μm (\bar{x} = 11.6 × 3.7 μm, n = 25). *Conidia* fusoid to ellipsoid, straight to slightly curved, 4-septate, 19.8–24.7 × 6.7–9.4 μm (\bar{x} = 21.7 × 7.8 μm, n = 40), L/W ratio = 2.8; basal cell obconic with a truncate base, hyaline, rugose and thin-walled, 2.6–4.8 μm long (\bar{x} = 3.6 μm, n = 30); three median cells doliform, 13.3–18.2 μm (\bar{x} = 14.6 μm, n = 30) long, wall rugose, versicoloured, septa darker than the rest of the cell (second cell from the base pale brown to brown, 3.6–5.4 μm long; third cell brown, 4.7–6.8 μm long; fourth cell brown, 3.5–6.0 μm long); apical cell 3.0–5.0 μm (\bar{x} = 3.9 μm, n = 30) long, hyaline, conical to subcylindrical, thin- and smooth-walled, with 2–4 tubular apical appendages (mostly 3), arising from the apical crest, unbranched or branched at one appendage, filiform, flexuous, 15.0–33.0 μm (\bar{x} = 22.5 μm, n = 50) long; basal appendage single, tubular, unbranched, centric, 2.1–5.7 μm (\bar{x} = 4.1 μm, n = 30) long.

Description from JZB340114 (Figure 5.27): **Sexual morph:** Not observed. **Asexual morph:** *Conidiomata* globose, solitary or gregarious, semi-immersed or superficial, exuding globose, black conidial masses. *Conidiophores* indistinct, often reduced to conidiogenous cells. *Conidiogenous cells* discrete, ampulliform, flask-shaped or obclavate, hyaline, 7.5–18.2 × 2.2–4.9 μm (\bar{x} = 11.6 × 3.4 μm, n = 30). *Conidia* fusoid to ellipsoid, straight to slightly curved, 4-septate, 15.9–23.2 × 5.6–8.2

μm ($\bar{x} = 19.0 \times 6.9 \mu\text{m}$, $n = 40$), L/W ratio = 2.7; basal cell obconic with a truncate base, hyaline, rugose and thin-walled, 2.6–5.8 μm long ($\bar{x} = 3.6 \mu\text{m}$, $n = 30$); three median cells doliiform, 11.1–14.9 μm ($\bar{x} = 12.8 \mu\text{m}$, $n = 30$) long, wall rugose, versicoloured, septa darker than the rest of the cell (second cell from the base pale brown to brown, 3.1–5.8 μm long; third cell brown, 3.5–6.3 μm long; fourth cell brown, 3.3–4.9 μm long); apical cell 2.4–5.2 μm ($\bar{x} = 3.1 \mu\text{m}$, $n = 30$) long, hyaline, conical to subcylindrical, thin- and smooth-walled, with 2–3 tubular apical appendages (mostly 2), arising from the apical crest, unbranched or branched at one appendage, filiform, flexuous, 13.2–26.7 μm ($\bar{x} = 19.0 \mu\text{m}$, $n = 50$) long; basal appendage single, tubular, unbranched, centric, 2.5–7.2 μm ($\bar{x} = 4.7 \mu\text{m}$, $n = 30$) long.

Culture characteristics – Colonies on PDA reaching 62–67 mm diam. after four days at 25°C with undulate edge, concentric, white, becoming buff after three weeks with dense felt mycelium, and produce abundant black conidiomata.

Material examined – China, Fujian Province, Longyan City, from diseased stems of *Vaccinium corymbosum*, May 2023, X. H. Li and Y. Y. Zhou (dry cultures JZBH340112–JZBH340113), living cultures JZB340112–JZB340113; Guizhou Province, Majiang County, from diseased leaves of *Vaccinium corymbosum*, May 2023, X. H. Li and Y. Y. Zhou (dry cultures JZBH340114–JZBH340115), living cultures JZB340114–JZB340115.

Notes – In the phylogenetic tree, four new isolates (JZB340112–JZB340115) formed two clades related to *Neo. haikouensis* and *Neo. terricola*. Sequences of JZB340112 and JZB340113 have 5 nucleotide differences (ITS: 1/550; tef1: 3/450; tub2:1/520) from *Neo. haikouensis*, and 3 nucleotide differences (tef1: 2/450; tub2: 1/520) from *Neo. terricola*; sequences of JZB340114 and JZB340115 have 5 nucleotide differences (ITS: 1/550; tub2: 4/520) from *Neo. haikouensis*, and 2 nucleotide differences (tub2: 2/520) from *Neo. terricola*. To confirm the relationship of the two clades, representative isolates (JZB340113 and JZB340114) was selected to observe morphology respectively. The comparison of morphological characters among *Neo. haikouensis*, *Neo. terricola* and the two clades was shown in table 3. The dimension of conidial size, apical appendages and basal appendages are similar, while the conidiogenous cells of *Neo. terricola* are shorter than the other three (2.5–3.5 \times 2–3 μm vs. 5.0–10.0 \times 2.0–6.0 μm in *Neo. haikouensis*, 6.2–17.6 \times 2.0–5.2 μm in JZB340113

and $7.5\text{--}18.2 \times 2.2\text{--}4.9 \mu\text{m}$ in JZB340114). The characters of culture are slightly different between JZB340113 and JZB340114, for the colony of JZB340113 showed more obvious concentric character in the early stage, it may be because of the difference between isolates. The morphology between *Neo. haikouensis* and *Neo. terricola* was indistinguishable, while *Neo. haikouensis* (Zhang et al., 2022) was introduced before *Neo. terricola* (Li et al., 2022). Therefore, we identified all the four new isolates as *Neo. haikouensis*. Whether *Neo. terricola* will be synonymized under *Neo. haikouensis* need to be further studied. *Neo. haikouensis* was introduced by Zhang et al. (2022) from diseased leaves of *Ilex chinensis* in China. This is the first report of *Neo. haikouensis* on blueberry (*Vaccinium* spp.).

Figure 5.26 Morphological characters of *Neopestalotiopsis haikouensis* (JZB340113)

Figure 5.26 a Colony on PDA after four days; b Colony on PDA after three weeks; c Conidiomata on PDA; d–f Conidiogenous cells; g–i Conidia; Scale bars: c=1000 μm ; d–f=20 μm ; g–i=10 μm

Figure 5.27 Morphological characters of *Neopestalotiopsis haikouensis* (JZB340114)

Figure 5.27 a Colony on PDA after four days; b Colony on PDA after three weeks; c Conidiomata on PDA; d–f Conidiogenous cells; g–j Conidia; Scale bars: d–f=10 μm .

Neopestalotiopsis iberica E. Diogo, M.H. Bragança & A.J.L. Phillips, in Diogo, Gonçalves, Silva, Valente, Bragança & Phillips, Mycol. Progr. 20(11): 1449 (2021).

Associated with stem blight of *Vaccinium* spp. For morphological description, see Diogo et al. (2021).

Material examined – China, Liaoning Province, Huludao City, from stem blight of *Vaccinium corymbosum*, April 2023, X. H. Li (dried culture JZBH340116–JZBH340117), living cultures JZB340116–JZB340117; *ibid.*, Jilin Province, Gongzhuling City, from stem blight of *Vaccinium angustifolium*, June 2023, X. H. Li, Y. Y. Zhou & P. Z. Chen (dried culture JZBH340118), living cultures JZB340118.

Notes – In the phylogenetic analysis, three isolates obtained in the current study (JZB340116–JZB340118) clustered together with reference isolates of *Neopestalotiopsis iberica* (including ex-type CBS 147688) with 95% ML bootstrap support and 1.00 Bayesian posterior probabilities. And the morphological characters of our isolates resemble to the type description of *Neo. iberica* (Diogo et al., 2021). *Neopestalotiopsis iberica* was introduced by Diogo et al. (2021) from diseased leaf and stem of *Eucalyptus globulus* in Portugal and Spain. In China, the species has been reported to cause leaf spots on *Camellia oleifera* and *Synsepalum dulcificum* (Li et al., 2021; You et al., 2024). The three isolates generated in this study were identified as *Neopestalotiopsis iberica* as a new host record on *Vaccinium* spp.

Neopestalotiopsis jiangxiensis P. Razaghi, F. Liu & L. Cai, in Razaghi, Raza, Han, Ma, Cai, Zhao, Chen, Phurbu & Liu, Stud. Mycol. 109: 226 (2024).

Associated with stem blight of *Vaccinium angustifolium*. For morphological description and illustration, see Razaghi et al. (2024).

Material examined – China, Jilin Province, Gongzhuling City, from stem blight of *Vaccinium angustifolium*, June 2023, X. H. Li, Y. Y. Zhou and P.Z. Chen (dried cultures JZBH340119–JZBH340120), living cultures JZB340119–JZB340120.

Notes – In the phylogenetic tree, two isolates obtained in the current study (JZB340119–JZB340120) clustered with the ex-type of *Neopestalotiopsis jiangxiensis* (CBS 114159) with 85% bootstrap support and 1.00 posterior probabilities. And the morphological characters are similar to description of *Neo. jiangxiensis* (Razaghi et al., 2024). *Neopestalotiopsis jiangxiensis* was introduced from *Rhododendron latoucheae* (Ericaceae) in China (Razaghi et al., 2024), and *R. latoucheae* was the only host

reported previously. This is the first report of *Neo. jiangxiensis* on *Vaccinium angustifolium*, which also belong to Ericaceae.

Neopestalotiopsis keteleeriae (Y. Song, K.D. Hyde & Yong Wang bis) P. Razaghi, F. Liu & L. Cai, in Razaghi, Raza, Han, Ma, Cai, Zhao, Chen, Phurbu & Liu, Stud. Mycol. 109: 229 (2024).

Associated with stem blight of *Vaccinium corymbosum*. For morphological description, see Song et al. (2014).

Material examined – China, Fujian Province, Longyan City, from stem blight of *Vaccinium corymbosum*, May 2023, X. H. Li and Y. Y. Zhou (dried culture JZBH340121–JZBH340122), living cultures JZB340121–JZB340122.

Notes – In the phylogenetic analysis, two isolates obtained in the current study (JZB340121 and JZB340122) clustered with reference isolates of *Neopestalotiopsis keteleeriae* (including ex-type MFLUCC 13-0915) with 62% bootstrap support and 1.00 posterior probabilities. The morphological characters of our isolates resemble to the type description of *Neo. keteleeriae* (Song et al., 2014). *Neopestalotiopsis keteleeriae* was introduced by Song et al. (2014) as '*Pestalotiopsis keteleeria*' from diseased leaves of *Keteleeria* in China. Soon after, Maharachchikumbura et al. (2014) proposed the genus *Neopestalotiopsis*, to accommodate segregates of *Pestalotiopsis*, comprising the clade in which '*Pestalotiopsis keteleeria*' located, while '*Pestalotiopsis keteleeria*' was not included in the data set. The species was referred to as '*Neopestalotiopsis keteleeria*' or '*Neo. keteleerie*' in the subsequent publications (Senanayake et al., 2020; Li et al., 2021; Yang et al., 2021). However, Razaghi et al. (2024) found that the sequence of transcription factor (*tef*) of ex-type (MFLUCC 13-0915) in these publications was inconsistent with that in the original publication. According to the latest classification, *Neopestalotiopsis keteleeriae* was officially established as a new combination, and *Neo. rhapsidis* (introduced by Yang et al. in 2021 from leaf spots of *Rhapis excelsa* in China) was synonymised under *Neo. keteleeriae* (Razaghi et al., 2024). This is the first report of *Neopestalotiopsis keteleeriae* on *Vaccinium* spp.

Neopestalotiopsis photiniae Y.R. Sun & Yong Wang bis, in Sun, Jayawardena, Sun & Wang, Microbiology Spectrum: e03987-22, 6 (2023). Figure 5.28

Associated with leaf spot of *Vaccinium corymbosum*. **Sexual morph:** Not observed. **Asexual morph:** *Conidiomata* globose, gregarious, semi-immersed or superficial, exuding globose, black conidial masses. *Conidiophores* indistinct, often reduced to conidiogenous cells. *Conidiogenous cells* discrete, ampulliform, flask-shaped or obclavate, hyaline, $8.0\text{--}17.0 \times 2.9\text{--}5.2 \mu\text{m}$ ($\bar{x} = 12.4 \times 3.9 \mu\text{m}$, $n = 25$). *Conidia* fusoid to ellipsoid, straight to slightly curved, 4-septate, $17.0\text{--}25.6 \times 6.5\text{--}8.9 \mu\text{m}$ ($\bar{x} = 20.6 \times 7.9 \mu\text{m}$, $n = 40$), L/W ratio = 2.6; basal cell obconic with a truncate base, hyaline, rugose and thin-walled, $2.1\text{--}5.4 \mu\text{m}$ long ($\bar{x} = 3.4 \mu\text{m}$, $n = 30$); three median cells doliiiform, $11.6\text{--}16.8 \mu\text{m}$ ($\bar{x} = 14.6 \mu\text{m}$, $n = 30$) long, wall rugose, versicoloured, septa darker than the rest of the cell (second cell from the base pale brown to brown, $2.9\text{--}5.9 \mu\text{m}$ long; third cell brown, $3.7\text{--}6.5 \mu\text{m}$ long; fourth cell brown, $3.0\text{--}5.9 \mu\text{m}$ long); apical cell $2.7\text{--}5.1 \mu\text{m}$ ($\bar{x} = 3.5 \mu\text{m}$, $n = 30$) long, hyaline, conical to subcylindrical, thin- and smooth-walled, with 2–3 tubular apical appendages (mostly 3), arising from the apical crest, unbranched or branched at one appendage, filiform, flexuous, $18.7\text{--}39.3 \mu\text{m}$ ($\bar{x} = 23.5 \mu\text{m}$, $n = 50$) long; basal appendage single, tubular, unbranched, centric, $3.9\text{--}8.4 \mu\text{m}$ ($\bar{x} = 5.7 \mu\text{m}$, $n = 30$) long.

Culture characteristics – Colonies on PDA reaching 58 mm diam. after four days at 25°C, concentric with undulate edge, colony white, becoming pale yellow after three weeks.

Material examined – China, Guizhou Province, Majiang County, from diseased leaves of *Vaccinium corymbosum*, May 2023, X. H. Li and Y. Y. Zhou (dry cultures JZBH340123– JZBH340124), living cultures JZB340123– JZB340124.

Notes – In the phylogenetic tree, the two new isolates from this study (JZB340123 and JZB340124) clustered close to *Neopestalotiopsis photiniae* (MFLUCC 22-0129) with 100% ML bootstrap support and 1.00 Bayesian posterior probabilities. Sequences of the two new isolates have 3 nucleotide differences in tub2 from *Neo. photiniae*. The comparison of morphological characters between the new isolates and *Neo. photiniae* was shown in table 3. Most morphological characters of the isolates are similar to the description of the ex-type of *Neo. photiniae* except for longer conidiogenous cells ($8.0\text{--}17.0 \mu\text{m}$ vs. $1\text{--}3 \mu\text{m}$), and faster growth rate of the culture

(Sun et al., 2023). However, the phylogenetic relationship and other highly overlapped morphological characters could not support the establish of the new species. Therefore, we identify the two isolates as *Neo. photiniae*. *Neopestalotiopsis photiniae* was introduced from *Photinia serratifolia* leaf spot in Guizhou Province, China (Sun et al., 2023). This is the first report of *Neo. photiniae* on blueberry (*Vaccinium* spp.), also from leaf spot disease in Guizhou Province. Therefore, we speculate that *Neo. photiniae* could be a common plant pathogen in Guizhou Province in China.

Figure 5.28 Morphological characters of *Neopestalotiopsis photiniae* (JZB340123)

Figure 5.28 a Colony on PDA after four days; b Colony on PDA after three weeks; c Conidiomata on PDA; d–f Conidiogenous cells; g–i Conidia; Scale bars: c = 500 μm ; d–i = 10 μm

Neopestalotiopsis protearum (Crous & L. Swart) Maharachch., K.D. Hyde & Crous, in Maharachchikumbura, Hyde, Groenewald, Xu & Crous, Stud. Mycol. 79: 147 (2014). Figure 5.29

Associated with leaf spot of *Vaccinium corymbosum*. **Sexual morph:** Not observed. **Asexual morph:** *Conidiomata* globose, solitary or gregarious, semi-immersed or immersed, exuding globose, black conidial masses, 334–780 µm diam (\bar{x} = 560 µm, n = 10). *Conidiophores* indistinct, often reduced to conidiogenous cells. *Conidiogenous cells* discrete, ampulliform, flask-shaped or obclavate, hyaline, 7.5–12 × 2–6 µm (\bar{x} = 9.0 × 4.0 µm, n = 30). *Conidia* fusoid to ellipsoid, straight to slightly curved, 4-septate, 21–25 × 6.5–8 µm (\bar{x} = 23.0 × 7.3 µm, n = 30), L/W ratio = 3.1; basal cell obconic with a truncate base, hyaline, rugose and thin-walled, 3–5 µm long (\bar{x} = 4.0 µm, n = 30); three median cells doliiform, 15–16.5 µm (\bar{x} = 15.7 µm, n = 30) long, wall rugose, versicoloured, septa darker than the rest of the cell (second cell from the base pale brown, 4–5 µm long; third cell brown, 5–6.5 µm long; fourth cell brown, 4.5–6 µm long); apical cell 3–5 µm (\bar{x} = 4.0 µm, n = 30) long, hyaline, conical to subcylindrical, thin- and smooth-walled, with 3 tubular apical appendages, arising from the apical crest, unbranched, filiform, flexuous, 13–20 µm (\bar{x} = 17.1 µm, n = 30) long; basal appendage single, tubular, unbranched, centric, 4.5–6.5 µm (\bar{x} = 5.3 µm, n = 30) long.

Culture characteristics – Colonies on PDA reaching 67 mm diam. after four days at 25°C, flat with lobate edge, concentric, white, aerial mycelium sparse, flocculence.

Material examined – China, Fujian Province, Longyan City, from diseased leaves of *Vaccinium corymbosum*, May 2023, X. H. Li and Y. Y. Zhou (dry cultures JZBH340125– JZBH340126), living cultures JZB340125– JZB340126.

Notes – The two new isolates from this study (JZB340125 and JZB340126) phylogenetically close to the ex-type of *Neopestalotiopsis protearum* (CBS 114178). The morphology of the isolates is also similar to the description of the ex-type of *Neo. protearum* (Maharachchikumbura et al., 2014). The two isolates are identified as *Neo. collariata*. *Neopestalotiopsis protearum* was originally introduced as *Pestalotiopsis protearum* from *Leucospermum cuneiforme* in Zimbabwe, associated with leaf spot (Crous et al., 2011). Subsequently *Pes. protearum* was transferred to *Neopestalotiopsis*,

and was assigned as the type species of *Neopestalotiopsis* (Maharachchikumbura et al., 2014). *Neopestalotiopsis protearum* has been also reported to cause seed rot on *Camellia oleifera* in China (Tang et al., 2021). This is the first report of *Neo. protearum* on blueberry (*Vaccinium* spp.).

Figure 5.29 Morphological characters of *Neopestalotiopsis protearum* (JZB340126)

Figure 5.29 a Colony on PDA after four days; b Colony on PDA after three weeks; c Conidiomata on PDA; d–e Conidiogenous cells; f–g Conidia; Scale bars: c=500 μ m; d–g=10 μ m.

Neopestalotiopsis rosae Maharachch., K.D. Hyde & Crous, in Maharachchikumbura, Hyde, Groenewald, Xu & Crous, Stud. Mycol. 79: 147 (2014).

Associated with leaf spot, stem blight and root rot of *Vaccinium* spp. For morphological description, see Maharachchikumbura et al. (2014).

Material examined – China, Liaoning Province, Dandong City, from stem blight of *Vaccinium* sp., March 2023, X. H. Li and L. N. Wu (dried culture JZBH340127), living cultures JZB340127; *ibid.*, from root rot of *Vaccinium* sp., March 2023, X. H. Li and L. N. Wu (dried culture JZBH340128–JZBH340129), living cultures JZB340128–JZB340129; *ibid.*, Huludao City, from root rot of *Vaccinium corymbosum*, April 2023, X. H. Li (dried culture JZBH340130–JZBH340131), living cultures JZB340130–JZB340131; *ibid.*, from stem blight of *Vaccinium corymbosum*, April 2023, X. H. Li (dried culture JZBH340132–JZBH340134), living cultures JZB340132–JZB340134; *ibid.*, Guizhou Province, Majiang County, from leaf spot of *Vaccinium virgatum*, May 2023, X. H. Li and Y. Y. Zhou (dried culture JZBH340135), living cultures JZB340135; *ibid.*, Heilongjiang Province, Harbin City, from stem blight of *Vaccinium* sp., June 2023, X. H. Li, Y. Y. Zhou and P. Z. Chen (dried culture JZBH340136), living cultures JZB340136.

Notes – In the phylogenetic analysis, seven isolates obtained in the current study (JZB340127–JZB340136) clustered with reference isolates of *Neopestalotiopsis rosae* (including ex-type CBS 101057). The morphological characters of our isolates resemble to the type description of *Neo. rosae* (Maharachchikumbura et al., 2014). *Neopestalotiopsis rosae* was initially isolated from stem lesion of *Rosa* sp. in New Zealand and stem of *Paeonia suffruticosa* in USA (Maharachchikumbura et al., 2014). In China, the species has been reported to cause root rot of strawberry (*Fragaria × ananassa*) (Sun et al., 2021) and leaf or fruit spot of pecan (*Carya illinoensis*) (Gao et al., 2022), Shatangju (*Citrus reticulata*) (Ma et al., 2023) and honeysuckle (*Lonicera caerulea*) (Yan et al., 2024). While on blueberry (*Vaccinium* spp.), stem blight and dieback caused by *Neo. rosae* were only reported in Peru and in Portugal (Rodríguez-Gálvez et al., 2020; Santos et al., 2022). This is the first report of *Neopestalotiopsis rosae* on blueberry (*Vaccinium* spp.) in China.

Neopestalotiopsis scalabiensis J. Santos, S. Hilário & A. Alves, Eur. J. Pl. Path. 162: 547 (2021)

Associated with stem blight of *Vaccinium* spp. For morphological description, see Santos et al. (2022).

Material examined – China, Liaoning Province, Huludao City, from stem blight of *Vaccinium corymbosum*, April 2023, X. H. Li (dried culture JZBH340137), living cultures JZB340137; *ibid.*, Jilin Province, Gongzhuling City, from stem blight of *Vaccinium angustifolium*, June 2023, X. H. Li, Y. Y. Zhou & P. Z. Chen (dried culture JZBH340138), living cultures JZB340138.

Notes – In the phylogenetic analysis, two isolates obtained in the current study (JZB340137 and JZB340138) clustered with the ex-type of *Neo. scalabiensis* (CAA1029). Morphologically our isolates resemble to the description of *Neo. scalabiensis* (Santos et al., 2022). *Neopestalotiopsis scalabiensis* was introduced by Santos et al. (2022) from stem and twig blight of *Vaccinium corymbosum* in Portugal. This is the first report of *Neo. scalabiensis* on blueberry (*Vaccinium* spp.) in China.

Neopestalotiopsis subepidermalis C. Peng & C.M. Tian, in Peng, Crous, Jiang, Fan, Liang & Tian, Persoonia 49: 230 (2022)

Associated with stem blight and root rot of *Vaccinium* spp. For morphological description, see Peng et al. (2022).

Material examined – China, Dandong City, from stem blight of *Vaccinium* sp., March 2023, X. H. Li and L.N. Wu (dried culture JZBH340139), living cultures JZB340139; *ibid.*, Liaoning Province, Huludao City, from root rot of *Vaccinium corymbosum*, April 2023, X. H. Li (dried culture JZBH340140), living cultures JZB340140.

Notes – In the phylogenetic analysis, two isolates obtained in the current study (JZB340139 and JZB340140) clustered with reference isolates of *Neopestalotiopsis subepidermalis* (including ex-type CFCC 55160) with 90% bootstrap support and 1.00 posterior probabilities. The morphological characters of our isolates resemble to the type description of *Neo. subepidermalis* (Peng et al., 2022). *Neopestalotiopsis subepidermalis* was introduced by Peng et al. (2022) from spines and branches of *Rosa* spp. in China. This is the first report of *Neopestalotiopsis subepidermalis* on blueberry (*Vaccinium* spp.).

Neopestalotiopsis vacciniicola J. Santos, S. Hilário & A. Alves, Eur. J. Pl. Path. 162: 546 (2021)

Associated with leaf spot and stem blight of *Vaccinium* spp. For morphological description, see Santos et al. (2022).

Material examined – China, Heilongjiang Province, Harbin City, from stem blight of *Vaccinium* sp., June 2023, X. H. Li, Y. Y. Zhou and P. Z. Chen (dried culture JZBH340141– JZBH340144), living cultures JZB340141– JZB340144; *ibid.*, Jilin Province, Gongzhuling City, from stem blight of *Vaccinium angustifolium*, June 2023, X. H. Li, Y. Y. Zhou and P. Z. Chen (dried culture JZBH340145– JZBH340156), living cultures JZB340145– JZB340156; *ibid.*, Liaoning Province, Ji'an City, from leaf spot of *Vaccinium corymbosum*, September 2023, X. H. Li (dried culture JZBH340157), living cultures JZB340157; *ibid.*, from stem blight of *Vaccinium corymbosum*, September 2023, X. H. Li (dried culture JZBH340158– JZBH340160), living cultures JZB340158– JZB340160.

Notes – In the phylogenetic analysis, twenty isolates obtained in the current study (JZBH340141–JZBH340160) clustered with reference isolates of *Neopestalotiopsis vacciniicola* (including ex-type MUM 21.35) with 99% bootstrap support and 1.00 posterior probabilities. The morphological characters of our isolates resemble to the type description of *Neo. vacciniicola* (Santos et al., 2022). *Neopestalotiopsis vacciniicola* was introduced by Santos et al., (2022) from twigs of highbush blueberry (*Vaccinium corymbosum*) with blight symptom in Portugal, with moderate virulence on blueberry in the pathogenicity test. This is also the only record of the species. In the current study, we first reported *Neopestalotiopsis vacciniicola* on *Vaccinium* spp. in China. And the species takes the highest percentage among the *Neopestalotiopsis*.

Pestalotiopsis Steyaert, Bull. Jard. bot. État Brux. 19: 300 (1949)

Classification: Sporocadaceae, Amphisphaeriales, Xylariomycetidae, Sordariomycetes, Ascomycota, Fungi (Hyde et al., 2024).

Notes: *Pestalotiopsis* was introduced by Steyaert (1949) with *Pestalotiopsis guepinii* as type species. The genus is characterized by 5-celled conidia with apical appendages (Maharachchikumbura et al., 2014). However, the taxonomy of *Pestalotiopsis* is confusing, for the species were previously named according to host associations, and

cryptic species in the genus need to be resolved (Maharachchikumbura et al., 2012). Maharachchikumbura et al. (2014) segregated the genus into *Neopestalotiopsis*, *Pestalotiopsis* and *Pseudopestalotiopsis* based on the morphological characters especially conidiogenous cells and colour of median conidial cells, combined with DNA data. Current *Pestalotiopsis* was considered to produce conidia with concolourous median cells (Maharachchikumbura et al., 2014). *Pestalotiopsis* is widely distributed in tropical and temperate regions as important plant pathogens and common endophytes, and also can switch life modes (Maharachchikumbura et al., 2012). As phytopathogens, the genus causes various diseases on plant leaves, shoots and fruits with widely host range especially fruit crops (Maharachchikumbura et al., 2014).

In this study, phylogenetic tree of *Pestalotiopsis* was constructed based on ITS, *tef 1- α* and *β -tub* sequence data using ML and Bayesian analyses, with *Neopestalotiopsis cubana* (CBS 600.96), *Neopestalotiopsis protearum* (CBS 114178), *Pseudopestalotiopsis cocos* (CBS 272.29) and *Pseudopestalotiopsis indica* (CBS 459.78) as outgroups (Figure 5.30). New isolates from this study clustered into thirteen clades, including seven clades close to *P. anhuiensis*, *P. clavata*, *P. foliicola*, *P. hainanensis*, *P. kenyana*, *P. rhodomyrti*, *P. tumida*, three ambiguous clades, as well as three single clades. Combined with morphological characters, three new species *Pestalotiopsis caulicola*, *Pestalotiopsis fujianensis* and *Pestalotiopsis vaccinii* were introduced.

Figure 5.30 (continued)

Figure 5.30 The alignment comprises 1,676 characters with gaps. The tree is rooted with *Neopestalotiopsis cubana* (CBS 600.96), *Neopestalotiopsis protearum* (CBS 114178), *Pseudopestalotiopsis cocos* (CBS 272.29) and *Pseudopestalotiopsis indica* (CBS 459.78). The tree topology of the ML analysis was similar to the Bayesian analysis. The best-scoring RAXML tree with a final likelihood value of -19012.665673 is presented. The matrix had 905 distinct alignment patterns, with 9.20% of undetermined characters or gaps. Estimated base frequencies were as follows: A = 0.237741, C = 0.295298, G = 0.212298, T = 0.254663; substitution rates AC = 0.979184, AG = 3.599649, AT = 1.233153, CG = 1.000946, CT = 4.859047, GT = 1.000000; gamma distribution shape parameter $\alpha = 0.843840$. ML bootstrap support values $\geq 50\%$ and Bayesian posterior probabilities (BYPP) ≥ 0.90 are given near the nodes. The scale bar indicates the number of nucleotide changes per site. Ex-type strains are indicated in bold and newly generated sequences are indicated in red.

Pestalotiopsis caulicola sp. nov. Figure 5.31

Etymology – Named after the substrate origin from which it was isolated, stems.

Holotype – JZBH340161

Associated with stem blight of *Vaccinium corymbosum*. **Sexual morph:** Not observed. **Asexual morph:** *Conidiomata* in culture subglobose to globose, aggregated or solitary, black, epidermal to subepidermal, exuding black conidial masses. *Conidiophores* indistinct, often reduced to conidiogenous cells. *Conidiogenous cells* discrete, cylindrical to subcylindrical or ampulliform to lageniform, $7.7\text{--}15.5 \times 2.2\text{--}3.2$ μm ($\bar{x} = 11.0 \times 2.7$ μm , $n = 30$). *Conidia* fusoid to ellipsoid, straight to slightly curved, 4-septate, $20.2\text{--}25.1 \times 5.3\text{--}6.6$ μm ($\bar{x} = 22.3 \times 5.9$ μm , $n = 40$), L/W ratio = 3.8; basal cell obconic with a truncate base, hyaline, thin-walled, $3.6\text{--}5.3$ μm long ($\bar{x} = 4.5$ μm , $n = 30$); three median cells doliiform, $12.6\text{--}16.1$ μm ($\bar{x} = 14.1$ μm , $n = 30$) long, concolorous, pale brown (second cell from the base $4.1\text{--}5.5$ μm long; third cell brown, $4.1\text{--}5.4$ μm long; fourth cell brown, $4.0\text{--}5.3$ μm long); apical cell $3.4\text{--}4.5$ μm ($\bar{x} = 3.8$ μm , $n = 30$) long, hyaline, conical to subcylindrical, thin- and smooth-walled, with 2–4 (mostly 3) tubular apical appendages, arising from the apical crest, unbranched or branched at one appendage, filiform, flexuous, $11.1\text{--}22.0$ μm ($\bar{x} = 16.0$ μm , $n = 50$) long; basal appendage single, tubular, unbranched, centric, $4.7\text{--}9.0$ μm ($\bar{x} = 6.5$ μm , $n = 30$) long.

Culture characteristics – Colonies on PDA reaching 68 mm diam. after five days at 25°C, flat with entire edge, aerial mycelium sparse, pale yellow.

Typus – China, Fujian Province, Longyan City, from diseased stems of *Vaccinium corymbosum*, May 2023, X. H. Li and Y. Y. Zhou (holotype dry culture JZBH340161, ex-type living culture JZB340161).

Additional material examined – China, Fujian Province, Longyan City, from diseased stems of *Vaccinium corymbosum*, May 2023, X. H. Li and Y. Y. Zhou (dry culture JZBH340162, living culture JZB340162).

Notes – Three isolates of *Pestalotiopsis caulicola* (JZB340161 and JZB340162) formed a distinct clade close to *Pes. aggestorum*, *Pes. colombiensis* and *Pes. silvicola*, with 14 bp nucleotide differences (9 bp in *tef*, 5 bp in *tub*) from *Pes. aggestorum*; 10 bp nucleotide differences (1 bp in ITS, 1 bp in *tef*; 8 bp in *tub*) from *Pes. colombiensis*; and 14 bp nucleotide differences (ITS: 1 bp; *tef*: 9 bp; *tub*: 4 bp) from *Pes. silvicola*.

Morphologically, *Pes. caulicola* differs from *Pes. aggestorum* by relatively shorter apical appendages (11.1–22.0 μm vs. 18–28.0 μm) and number of basal appendages (single vs. 1–2); from *Pes. colombiensis* by relatively longer basal appendages (4.7–9.0 μm vs. 2–5 μm); from *Pes. silvicola* by relatively thinner conidia (5.3–6.6 μm vs. 6(6.5)–7.5(–8.5) μm) and number of basal appendages (single vs. 1–2). Overall, differences of the morphology characters among the four species are not distinct. Combined phylogeny and morphology, we introduce *Pes. caulicola* as a new species.

Figure 5.31 Morphological characters of *Pestalotiopsis caulicola* (JZB340161)

Figure 5.31 a Colony on PDA after four days; b Colony on PDA after three weeks; c Conidiomata on PDA; d–e Conidiogenous cells; f–h Conidia; Scale bars: d–h=10 μm .

Pestalotiopsis fujianensis sp. nov. Figure 5.32

Etymology – Named after the province where the fungus was collected, Fujian Province.

Holotype – JZBH340163

Associated with leaf spot of *Vaccinium corymbosum*. **Sexual morph:** Not observed. **Asexual morph:** *Conidiomata* in culture subglobose to globose, aggregated or solitary, black, epidermal to subepidermal, exuding black conidial masses. *Conidiophores* indistinct, often reduced to conidiogenous cells. *Conidiogenous cells* discrete, cylindrical to subcylindrical or ampulliform to lageniform, $8.8\text{--}14.1 \times 2.5\text{--}4.3 \mu\text{m}$ ($\bar{x} = 10.6 \times 3.5 \mu\text{m}$, $n = 20$). *Conidia* fusoid to ellipsoid, straight to slightly curved, 4-septate, $18.9\text{--}25.5 \times 6.0\text{--}8.8 \mu\text{m}$ ($\bar{x} = 21.8 \times 6.9 \mu\text{m}$, $n = 30$), L/W ratio = 3.1; basal cell obconic with a truncate base, hyaline, thin-walled, $3.2\text{--}4.8 \mu\text{m}$ long ($\bar{x} = 4.0 \mu\text{m}$, $n = 30$); three median cells doliiform, $12.1\text{--}15.2 \mu\text{m}$ ($\bar{x} = 13.3 \mu\text{m}$, $n = 30$) long, concolorous, pale brown (second cell from the base $4.1\text{--}5.6 \mu\text{m}$ long; third cell brown, $4.5\text{--}5.8 \mu\text{m}$ long; fourth cell brown, $4.6\text{--}5.4 \mu\text{m}$ long); apical cell $3.6\text{--}3.9 \mu\text{m}$ ($\bar{x} = 3.7 \mu\text{m}$, $n = 30$) long, hyaline, conical to subcylindrical, thin- and smooth-walled, with 2–4 (mostly 3) tubular apical appendages, arising from the apical crest, unbranched or branched at one appendage, filiform, flexuous, $16.5\text{--}26.2 \mu\text{m}$ ($\bar{x} = 20.8 \mu\text{m}$, $n = 30$) long; basal appendage single, tubular, unbranched, centric, $5.1\text{--}11.2 \mu\text{m}$ ($\bar{x} = 8.5 \mu\text{m}$, $n = 30$) long.

Culture characteristics – Colonies on PDA reaching 48 mm diam. after five days at 25°C, flat with entire edge, aerial mycelium sparse, pale yellow.

Typus – China, Fujian Province, Longyan City, from diseased stems of *Vaccinium corymbosum*, May 2023, X. H. Li and Y. Y. Zhou (holotype dry culture JZBH340163, ex-type living culture JZB340163).

Additional material examined – China, Fujian Province, Longyan City, from diseased leaves of *Vaccinium corymbosum*, May 2023, X. H. Li and Y. Y. Zhou (dry culture JZBH340164, living cultures JZB340164).

Notes – *Pestalotiopsis fujianensis* (JZB340163 and JZB340164) formed a distinct lineage and was sister to *Pes. changjiangensis* in the phylogenetic tree with 77% ML bootstrap value and 1.00 Bayesian posterior probabilities, with 51 bp different in sequences (ITS: 9bp; tef: 29bp; tub: 13bp). Morphologically, *P. fujianensis* differs

from *Pes. changjiangensis* by longer conidiogenous cells (8.8–14.1 μm versus 3.5 to 6 μm), and longer apical appendages (16.5–26 μm versus 1.5 to 7 μm), as well as the existence and absent of basal appendage in *Pestalotiopsis fujianensis* and *Pes. changjiangensis* respectively (Jiang et al., 2022). The comparison was shown in Table 4. Therefore, we introduce *Pes. fujianensis* as a new species based on phylogeny and morphology.

Figure 5.32 a Colony on PDA after four days; b Colony on PDA after three weeks; c Conidiomata on PDA; d–f Conidiogenous cells; g–j Conidia; Scale bars: c=500 μm ; d–j=20 μm .

Pestalotiopsis vaccinii sp. nov. Figure 5.33

Etymology – Named after the host species from which it was isolated, *Vaccinium* spp.

Holotype – JZBH340166

Associated with leaf spot of *Vaccinium* spp. **Sexual morph:** Not observed. **Asexual morph:** *Conidiomata* in culture subglobose to globose, aggregated or solitary, black, epidermal to subepidermal, exuding black conidial masses. *Conidiophores* indistinct, often reduced to conidiogenous cells. *Conidiogenous cells* discrete, cylindrical to subcylindrical or ampulliform to lageniform, 8.1–18.2 × 2.0–3.5 µm (\bar{x} = 13.0 × 2.7 µm, n = 30). *Conidia* fusoid to ellipsoid, straight to slightly curved, 4-septate, 21.4–28.5 × 7.7–9.9 µm (\bar{x} = 24.5 × 8.7 µm, n = 40), L/W ratio = 2.8; basal cell obconic with a truncate base, hyaline, thin-walled, 2.7–5.9 µm long (\bar{x} = 4.5 µm, n = 30); three median cells doliiform, 14.6–18.2 µm (\bar{x} = 16.4 µm, n = 30) long, concolorous, pale brown (second cell from the base 4.0–5.9 µm long; third cell brown, 4.8–6.2 µm long; fourth cell brown, 4.5–6.4 µm long); apical cell 3.0–5.5 µm (\bar{x} = 3.8 µm, n = 30) long, hyaline, conical to subcylindrical, thin- and smooth-walled, with 2–5 (mostly 3) tubular apical appendages, arising from the apical crest, unbranched or branched at one appendage, filiform, flexuous, 8.7–26.6 µm (\bar{x} = 16.7 µm, n = 50) long; basal appendage single, tubular, unbranched, centric, 5.1–14.6 µm (\bar{x} = 8.1 µm, n = 30) long.

Culture characteristics – Colonies on PDA reaching 48 mm diam. after five days at 25°C, flat with entire edge, aerial mycelium sparse, pale yellow.

Typus – China, Guizhou Province, Majiang County, from diseased leaves of *Vaccinium corymbosum*, May 2023, X. H. Li and Y. Y. Zhou (holotype dry culture JZBH340166, ex-type living culture JZB340166).

Additional material examined – China, Fujian Province, Longyan City, from diseased leaves of *Vaccinium corymbosum*, May 2023, X. H. Li and Y. Y. Zhou (dry cultures JZBH340165, living cultures JZB340165); Guizhou Province, Majiang County, from diseased leaves of *Vaccinium virgatum*, May 2023, X. H. Li and Y. Y. Zhou (dry cultures JZBH340167, living cultures JZB340167).

Notes – In the phylogenetic analysis, *Pes. vaccinii* (JZB340165– JZB340167) closely related to *Pes. rhododendri*, with 3 nucleotide differences (2 bp in ITS and 3 bp in tub) to the ex-type of *Pes. rhododendri* (IFRDCC 2399). Morphologically, JZB340138 differs from *Pes. rhododendri* by relatively wider conidia ($21.4\text{--}28.5 \times 7.7\text{--}9.9$ vs. $(16)18\text{--}27(29) \times 5\text{--}8 \mu\text{m}$), and longer basal appendages ($5.1\text{--}14.6$ vs. $2\text{--}6$), as well as the number of apical appendage ($2\text{--}5$ (mostly 3) vs. 3). The morphological comparison of the species in sister clade, *Pes. iberica* and *Pes. lushanensis*, was also provided in table 4. Here we introduced *Pes. vaccinii* as a new species combined phylogeny and morphology.

Figure 5.33 Morphological characters of *Pestalotiopsis vaccinii* (JZB340166)

Figure 5.33 a Colony on PDA after four days; b Colony on PDA after three weeks; c Conidiomata on PDA; d–f Conidiogenous cells; g–j Conidia; Scale bars: d–j =20 μm .

***Pestalotiopsis* sp.1** Figure 5.34

Associated with leaf spot of *Vaccinium corymbosum*. **Sexual morph:** Not observed. **Asexual morph:** *Conidiomata* in culture subglobose to globose, aggregated or solitary, black, epidermal to subepidermal, exuding black conidial masses. indistinct, often reduced to conidiogenous cells. *Conidiogenous cells* discrete or integrated, ampulliform, cylindrical or subcylindrical, hyaline, 7.1–14.0 \times 2.7–4.6 μm (\bar{x} = 10.3 \times 3.6 μm , n = 220). *Conidia* fusoid to ellipsoid, straight to slightly curved, 4-septate, 23.0–31.4 \times 5.8–7.7 μm (\bar{x} = 26.2 \times 6.6 μm , n = 40), L/W ratio = 4.0; basal cell obconic with a truncate base, hyaline, thin-walled, 3.5–5.8 μm long (\bar{x} = 4.6 μm , n = 30); three median cells doliiform, 13.0–17.5 μm (\bar{x} = 15.3 μm , n = 30) long, concolorous, (second cell from the base pale brown to brown, 4.2–6.4 μm long; third cell brown, 4.7–6.6 μm long; fourth cell brown, 4.3–6.8 μm long); apical cell 3.5–5.7 μm (\bar{x} = 4.3 μm , n = 30) long, hyaline, conical to subcylindrical, thin- and smooth-walled, with 2–3 (mostly 2) tubular apical appendages, arising from the apical crest, unbranched or branched at one appendage, filiform, flexuous, 9.7–23.5 μm (\bar{x} = 16.7 μm , n = 50) long; basal appendage present or absent, tubular, unbranched, centric, 1.8–6.3 μm (\bar{x} = 3.7 μm , n = 30) long.

Culture characteristics – Colonies on PDA reaching 61 mm diam. after five days at 25°C, flat with entire edge, aerial mycelium white, flocculent, forming black conidiomata with black conidial masses from colony centre; colony from reverse pale yellow in centre.

Material examined – China, Liaoning Province, Dandong City, from stems of *Vaccinium* sp. with blight symptoms, March 2023, X. H. Li and L. N. Wu (dry cultures JZBH340168), living cultures JZB340168.

Notes – In the phylogenetic analysis, the new isolate JZB340168 formed a sister clade to *Pes. clavata* and *Pes. pini* with low bootstrap value, but differs from *Pes. clavata* (MFLUCC 12-0268) in 12 bp nucleotide differences (3 bp in ITS, 6 bp in *tef* and 3 bp in *tub*); differs from *Pes. pini* (CBS 146841) in 16 bp nucleotide differences (2 bp in ITS, 12 bp in *tef* and 2 bp in *tub*). Morphologically, JZB340168 differs from *Pes. clavata* in larger mean conidium length/width ratio (4.0 vs. 3.1), and smaller basal

appendage (1.8–6.3 vs. 7–9); differs from *Pes. pini* in relatively shorter conidiogenous cells (7.1–14.0 × 2.7–4.6 μm vs 12–25 × 2–4 μm), larger mean conidium length/width ratio (4.0 vs. 3.2), and the number of apical appendages (2–3, mostly 2 vs 3–4, mostly 3) (table 5.4). The isolate JZB340138 probably a new species, but for the low bootstrap value, and special clade of *P. clavata* (see notes under *P. clavata*), further study is needed to confirm that.

Figure 5.34 Morphological characters of *Pestalotiopsis* sp.1 (JZB340168)

Figure 5.34 a Upper view Colony on PDA after four days; b Colony on PDA after three weeks; c Conidiomata on PDA; d–e Conidiogenous cells; f–i Conidia; Scale bars: d–i = 20 μm.

Pestalotiopsis anhuiensis Ning Jiang, in Jiang, Voglmayr, Xue, Piao & Li, *Persoonia*: 10.1128/spectrum.03272-22, 6 (2022). Figure 5.34

Associated with stem blight of *Vaccinium* spp. **Sexual morph:** Not observed. **Asexual morph:** *Conidiomata* in culture subglobose to globose, solitary or gregarious, semi-immersed or immersed, exuding black conidial masses. *Conidiophores* indistinct, often reduced to conidiogenous cells. *Conidiogenous cells* discrete, cylindrical to ampulliform, hyaline, 6.2–13.3 × 2.4–5.8 μm (\bar{x} = 9.3 × 3.3 μm, n = 20). *Conidia* fusoid to ellipsoid, straight to slightly curved, 4-septate, slightly constricted at the septa, 17.8–22.6 × 5.2–6.7 μm (\bar{x} = 20.7 × 5.8 μm, n = 30), L/W ratio = 3.5; basal cell obconic with a truncate base, hyaline, thin-walled, 2.8–4.5 μm long (\bar{x} = 3.6 μm, n = 30); three median cells doliiform, 12.7–15.5 μm (\bar{x} = 14.4 μm, n = 30) long, concolorous, (second cell from the base pale brown to brown, 3.7–4.6 μm long; third cell brown, 4.4–6.0 μm long; fourth cell brown, 4.3–5.8 μm long); apical cell 2.9–3.5 μm (\bar{x} = 3.3 μm, n = 30) long, hyaline, conical to subcylindrical, thin- and smooth-walled, with 2–3 tubular apical appendages, arising from the apical crest, unbranched or branched at one appendage, filiform, flexuous, 7.3–19.5 μm (\bar{x} = 13.2 μm, n = 30) long; basal appendage single, tubular, unbranched, centric, 3.1–5.6 μm (\bar{x} = 4.2 μm, n = 30) long.

Culture characteristics – Colonies on PDA reaching 60 mm diam. after five days at 25°C, flat with entire edge, aerial mycelium white, flocculent, forming black conidiomata with black conidial masses from colony centre; colony from reverse pale yellow in centre.

Material examined – China, Liaoning Province, Dandong City, from stem blight of *Vaccinium* sp., March 2023, X. H. Li and L. N. Wu (dry cultures JZBH340169–JZBH340170), living cultures JZB340169–JZB340170.

Notes – In the phylogenetic analysis, two new isolates of *Pes. anhuiensis* (JZB340169–JZB340170) clustered together with ex-type strain CFCC 54791. And morphological characters of the isolates are consistent with the description of *Pes. anhuiensis* (Jiang et al., 2022). *Pestalotiopsis anhuiensis* was introduced from *Cyclobalanopsis glauca* in China, associated with leaf diseases (Jiang et al., 2022). This is the first report of *Pes. anhuiensis* on blueberry (*Vaccinium* spp.).

Figure 5.35 Morphological characters of *Pestalotiopsis anhuiensis* (JZB340169)

Figure 5.35 a Colony on PDA after four days; b Colony on PDA after three weeks; c Conidiomata on PDA; d–e Conidiogenous cells; f–g Conidia; Scale bars: c=500 μm ; d=20 μm ; e–j=10 μm .

Pestalotiopsis clavata Maharachch. & K.D. Hyde, in Maharachchikumbura, Guo, Cai, Chukeatirote, Wu, Sun, Crous, Bhat, McKenzie, Bahkali & Hyde, Fungal Diversity 56(1): 108 (2012). Figure 5.36.

Associated with leaf spot and stem blight of *Vaccinium corymbosum*. **Sexual morph:** Not observed. **Asexual morph:** *Conidiomata* in culture subglobose to globose, aggregated or solitary, black, epidermal to subepidermal, exuding black conidial masses. *Conidiophores* cylindrical, branched at the base, hyaline. *Conidiogenous cells*

discrete or integrated, ampulliform, cylindrical or subcylindrical, hyaline, $8.2\text{--}16.0 \times 2.3\text{--}4.2 \mu\text{m}$ ($\bar{x} = 12.8 \times 3.0 \mu\text{m}$, $n = 30$). *Conidia* fusoid to ellipsoid, straight to slightly curved, 4-septate, $21.4\text{--}28.6 \times 7.1\text{--}9.8 \mu\text{m}$ ($\bar{x} = 24.2 \times 8.3 \mu\text{m}$, $n = 40$), L/W ratio = 2.9; basal cell obconic with a truncate base, hyaline, thin-walled, $3.2\text{--}6.0 \mu\text{m}$ long ($\bar{x} = 4.6 \mu\text{m}$, $n = 30$); three median cells doliiform, $14.5\text{--}18.3 \mu\text{m}$ ($\bar{x} = 16.0 \mu\text{m}$, $n = 30$) long, concolorous, (second cell from the base pale brown to brown, $4.0\text{--}6.7 \mu\text{m}$ long; third cell brown, $4.1\text{--}6.4 \mu\text{m}$ long; fourth cell brown, $4.5\text{--}5.9 \mu\text{m}$ long); apical cell $3.0\text{--}4.6 \mu\text{m}$ ($\bar{x} = 3.6 \mu\text{m}$, $n = 30$) long, hyaline, conical to subcylindrical, thin- and smooth-walled, with 2–3 tubular apical appendages, arising from the apical crest, unbranched or branched at one appendage, filiform, flexuous, $10.3\text{--}26.1 \mu\text{m}$ ($\bar{x} = 18.2 \mu\text{m}$, $n = 50$) long; basal appendage present or absent, 1–2, tubular, unbranched, centric, $1.8\text{--}8.4 \mu\text{m}$ ($\bar{x} = 5.1 \mu\text{m}$, $n = 30$) long.

Culture characteristics – Colonies on PDA reaching 61 mm diam. after five days at 25°C , flat with entire edge, aerial mycelium white, flocculent, forming black conidiomata with black conidial masses from colony centre; colony from reverse pale yellow in centre.

Material examined – China, Fujian Province, Longyan City, from stems of *Vaccinium corymbosum* with blight symptoms, May 2023, X. H. Li and Y. Y. Zhou (dry cultures JZBH340171), living cultures JZB340171; China, Guizhou Province, Majiang County, from leaf spot of *Vaccinium corymbosum*, May 2023, X. H. Li and Y. Y. Zhou (dry cultures JZBH340172), living cultures JZB340172.

Notes – The two new isolates (JZB340171– JZB340172) phylogenetically formed a clade closely related to *Pes. clavata* (MFLUCC 12-0268) with 3 bp nucleotide differences (1 bp in ITS, 1 bp in *tef* and 1 bp in *tub*). Their morphological characters are mostly overlapping, while JZB340171 has relative wider conidia ($21.4\text{--}28.6 \times 7.2\text{--}9.9 \mu\text{m}$ vs. $20\text{--}27 \times 6.5\text{--}8 \mu\text{m}$), and larger dimension range of basal appendage ($1.8\text{--}8.4 \mu\text{m}$ vs. $7\text{--}9 \mu\text{m}$). We also compared with the character with the strain *xs3* from another study (Rui et al., 2025), which have even wider conidia ($7.8\text{--}12.5 \mu\text{m}$). The difference in dimension may be because of different hosts or substrates. For the phylogenetical and morphological differences between our isolates and *Pes. clavata* are relatively small, we identified the new isolates as *Pes. clavata*. It's worth noting that another strain of *Pes. clavata* (MFLUCC 12-0269), which was originally introduced as *Pes. clavata* together with the ex-type (MFLUCC 12-0268), was not clustered together

with the ex-type strain, but located between *Pes. iberica* and *Pes. lushanensis* in the phylogenetic tree. MFLUCC 12-0269 has 1 bp nucleotide difference in ITS sequences and 9 bp differences in *tef-1 α* with the type strain. To resolve the phylogeny relationship of this branch, more approaches such as other informative gene loci are needed. *Pestalotiopsis clavata* was introduced as endophyte in living leaves of *Buxus* sp. and *Euonymus* sp. in China (Maharachchikumbura et al., 2012). Recently the species also reported as pathogen causing shoot blight on *Cedrus deodara* (Rui et al., 2025). In this study, *Pes. clavata* was first isolated from diseased stems on blueberry (*Vaccinium* spp.), which also be possible pathogen.

Figure 5.36 Morphological characters of *Pestalotiopsis clavata* (JZB340171)

Figure 5.36 a Colony on PDA after four days; b Colony on PDA after three weeks; c Conidiomata on PDA; d-f Conidiogenous cells; g-j Conidia; Scale bars: c=500µm; d=20µm; e-j=10 µm.

Pestalotiopsis foliicola Ning Jiang, in Jiang, Voglmayr, Xue, Piao & Li, Microbiology Spectrum: 10.1128/spectrum.03272-22, 13 (2022). Fig.5.37.

Associated with stem blight of *Vaccinium corymbosum*. **Sexual morph:** Not observed. **Asexual morph:** *Conidiomata* in culture subglobose to globose, solitary or gregarious, semi-immersed or immersed, exuding black conidial masses. *Conidiophores* indistinct, often reduced to conidiogenous cells. *Conidiogenous cells* discrete, cylindrical to ampulliform, hyaline, $8.2\text{--}19.0 \times 2.0\text{--}3.3 \mu\text{m}$ ($\bar{x} = 12.4 \times 2.5 \mu\text{m}$, $n = 20$). *Conidia* fusoid to ellipsoid, straight to slightly curved, 4-septate, slightly constricted at the septa, $19.6\text{--}24.1 \times 7.5\text{--}10.0 \mu\text{m}$ ($\bar{x} = 21.8 \times 8.7 \mu\text{m}$, $n = 40$), L/W ratio = 2.5; basal cell obconic with a truncate base, hyaline, thin-walled, $3.1\text{--}5.2 \mu\text{m}$ long ($\bar{x} = 4.2 \mu\text{m}$, $n = 30$); three median cells doliiiform, $13.6\text{--}16.1 \mu\text{m}$ ($\bar{x} = 14.8 \mu\text{m}$, $n = 30$) long, concolorous, (second cell from the base pale brown to brown, $4.0\text{--}6.4 \mu\text{m}$ long; third cell brown, $4.1\text{--}6.0 \mu\text{m}$ long; fourth cell brown, $3.9\text{--}5.5 \mu\text{m}$ long); apical cell $2.7\text{--}4.1 \mu\text{m}$ ($\bar{x} = 3.3 \mu\text{m}$, $n = 30$) long, hyaline, conical to subcylindrical, thin- and smooth-walled, with 2–3 tubular apical appendages (mostly 3), arising from the apical crest, unbranched or branched at one appendage, filiform, flexuous, $9.3\text{--}28.8 \mu\text{m}$ ($\bar{x} = 16.6 \mu\text{m}$, $n = 50$) long; basal appendage single, tubular, unbranched, centric, $1.4\text{--}7.0 \mu\text{m}$ ($\bar{x} = 3.8 \mu\text{m}$, $n = 30$) long.

Culture characteristics – Colonies on PDA reaching 67 mm diam. after five days at 25°C, flat with entire edge, aerial mycelium white, flocculent, forming black conidiomata with black conidial masses from colony centre; colony from reverse pale yellow in centre.

Material examined – China, Fujian Province, Longyan City, from diseased stems of *Vaccinium corymbosum*, May 2023, X. H. Li and Y. Y. Zhou (dry cultures JZBH340173– JZBH340174), living cultures JZB340173– JZB340174.

Notes – In the phylogenetic analysis, two new isolates (JZB340173– JZB340174) are closely related to *Pes. foliicola*. And morphological characters of the isolates are consistent with the description of *Pes. foliicola* (Jiang et al., 2022). *Pestalotiopsis foliicola* was introduced from diseased leaves of *Castanopsis faberi* in China, associated with leaf diseases (Jiang et al., 2022). This is the first report of *Pes. foliicola* on blueberry (*Vaccinium* spp.), which isolated from disease stems. The species might be a pathogen on different hosts.

Figure 5.37 Morphological characters of *Pestalotiopsis foliicola* (JZB340174)

Figure 5.37 a Colony on PDA after four days; b Colony on PDA after three weeks; c Conidiomata on PDA; d–e Conidiogenous cells; f–h Conidia; Scale bars: d=20 μm ; e–h=10 μm .

Pestalotiopsis hainanensis A.R. Liu, T. Xu & L.D. Guo, Fungal Diversity 24: 29 (2007)

Associated with stem blight of *Vaccinium corymbosum*.

Illustration and description: see Liu et al. (2013).

Material examined – China, Guizhou Province, Majiang County, from stem blight of *Vaccinium corymbosum*, May 2023, X. H. Li and Y. Y. Zhou (dried cultures JZBH340175– JZBH340176), living cultures JZB340175– JZB340176.

Notes – In the phylogenetic analysis, two isolates obtained in the current study (JZB340175–JZB340176) clustered with ex-type of *Pestalotiopsis hainanensis* (CNU060362) with 80% bootstrap support and 1.00 posterior probabilities. And the morphological characters are similar to the ex-type isolate of *Pes. hainanensis* (Liu et al., 2007). *Pestalotiopsis hainanensis* was introduced by Liu et al. (2007) as an endophyte from the stem of *Podocarpus macrophyllus* in China. This is the first report of *Pestalotiopsis hainanensis* on *Vaccinium* spp.

Pestalotiopsis kenyana Maharachch., K.D. Hyde & Crous, in Maharachchikumbura, Hyde, Groenewald, Xu & Crous, Stud. Mycol. 79: 166 (2014)

Associated with leaf spot and stem blight on *Vaccinium* spp. For morphological description, see Maharachchikumbura et al. (2014).

Material examined – China, Fujian Province, Longyan City, from leaf spot of *Vaccinium corymbosum*, May 2023, X. H. Li and Y. Y. Zhou (dried cultures JZBH340177– JZBH340187), living cultures JZB340177– JZB340187; *ibid.*, from stem blight of *Vaccinium corymbosum*, May 2023, X. H. Li and Y. Y. Zhou (dried cultures JZBH340188), living cultures JZB340188; China, Guizhou Province, Majiang County, from leaf spot of *Vaccinium corymbosum*, May 2023, X. H. Li and Y. Y. Zhou (dried cultures JZBH340189– JZBH340190), living cultures JZB340189– JZB340190; *ibid.*, from stem blight of *Vaccinium corymbosum*, May 2023, X. H. Li and Y. Y. Zhou (dried cultures JZBH340191), living cultures JZB340191; *ibid.*, from stem blight of *Vaccinium virgatum*, May 2023, X. H. Li and Y. Y. Zhou (dried cultures JZBH340192– JZBH340193), living cultures JZB340192– JZB340193.

Notes – In the phylogenetic analysis, seventeen isolates obtained in the current study (JZB340177– JZB340193) clustered with reference isolates of *Pestalotiopsis kenyana* (including ex-type CBS 442.67) with 91% bootstrap support and 1.00 posterior probabilities. And the morphological characters are similar to the ex-type isolate of *Pes. kenyana* (Maharachchikumbura et al., 2014). *Pestalotiopsis kenyana* was introduced by Maharachchikumbura et al., (2014) from the branch of *Coffea* sp. in Kenya. Subsequently the species has been reported to cause leaf blight of bayberry (*Myrica rubra*), prickly ash (*Zanthoxylum schinifolium*) and tea (*Camellia sinensis*) (Wang et al., 2019; Liu et al., 2021; Xun et al., 2023), as well as stem-end rot of mango fruits

(Tao et al., 2024). This is the first report of *Pestalotiopsis kenyana* on blueberry (*Vaccinium* spp.), which also could be common pathogen on blueberry.

Pestalotiopsis rhodomyrti Yu Song, K. Geng, K.D. Hyde & Yong Wang bis [as 'rhodomyrtus'], in Song, Geng, Zhang, Hyde, Zhao, Wei, Kang & Wang, Phytotaxa 126(1): 27 (2013)

Associated with leaf spot and stem blight of *Vaccinium corymbosum*. For morphological description, see Song et al. (2013).

Material examined – China, Fujian Province, Longyan City, from leaf spot of *Vaccinium corymbosum*, May 2023, X. H. Li and Y. Y. Zhou (dried cultures JZBH340194–JZBH340195), living cultures JZB340194– JZB340195; Guizhou Province, Majiang County, from leaf spot of *Vaccinium corymbosum*, May 2023, X. H. Li and Y. Y. Zhou (dried cultures JZBH340196), living cultures JZB340196; *ibid.*, Jilin Province, Ji'an City, from stem blight of *Vaccinium corymbosum*, September 2023, X. H. Li (dried cultures JZBH340197–JZBH340200), living cultures JZB340197–JZB340200.

Notes – In the phylogenetic analysis, eight isolates obtained in the current study (JZB340194–JZB340200) clustered with ex-type of *Pestalotiopsis rhodomyrtus* (LC3413) with 100% bootstrap support and 1.00 posterior probabilities. And the morphological characters are similar to the ex-type isolate of *Pes. rhodomyrtus* (Song et al., 2013). *Pestalotiopsis rhodomyrtus* was introduced by Song et al. (2013) from asymptomatic leaves of *Rhodomyrtus tomentosa* in China, and also has been reported on diseased tea plants (Liu et al., 2017), as well as on *Rosa* spp. (Peng et al., 2022). This is the first report of *Pestalotiopsis rhodomyrtus* on *Vaccinium* spp.

Pestalotiopsis tumida C. Peng & C.M. Tian, in Peng, Crous, Jiang, Fan, Liang & Tian, Persoonia 49: 235 (2022). Figure 5.38

Associated with leaf spot of *Vaccinium angustifolium*. **Sexual morph:** Not observed. **Asexual morph:** *Conidiomata* in culture subglobose to globose, solitary or gregarious, semi-immersed or immersed, exuding black conidial masses. *Conidiophores* indistinct, often reduced to conidiogenous cells. *Conidiogenous cells* discrete, cylindrical to ampulliform, hyaline, $7.3\text{--}10.8 \times 3.1\text{--}4.5 \mu\text{m}$ ($\bar{x} = 9.2 \times 3.6 \mu\text{m}$, $n = 20$). *Conidia* fusoid to ellipsoid, straight to slightly curved, 4-septate, slightly constricted at the septa, $19.5\text{--}24.8 \times 5.3\text{--}7.1 \mu\text{m}$ ($\bar{x} = 22.1 \times 6.2 \mu\text{m}$, $n = 30$), L/W ratio

= 3.6; basal cell obconic with a truncate base, hyaline, thin-walled, 2.6–5.3 μm long (\bar{x} = 3.6 μm , n = 30); three median cells doliiform, 14.5–17.3 μm (\bar{x} = 15.7 μm , n = 30) long, concolorous, (second cell from the base pale brown to brown, 4.3–5.4 μm long; third cell brown, 4.4–5.8 μm long; fourth cell brown, 4.4–6.1 μm long); apical cell 3.2–5.8 μm (\bar{x} = 4.2 μm , n = 30) long, hyaline, conical to subcylindrical, thin- and smooth-walled, with 2–3 tubular apical appendages (mostly 3), arising from the apical crest, unbranched, filiform, flexuous, 9.7–27.4 μm (\bar{x} = 17.6 μm , n = 50) long; basal appendage single, tubular, unbranched, centric, 5.9–15.6 μm (\bar{x} = 10.0 μm , n = 30) long.

Culture characteristics – Colonies on PDA reaching 60 mm diam. after five days at 25°C, flat with entire edge, aerial mycelium white, flocculent, forming black conidiomata with black conidial masses from colony centre; colony from reverse pale yellow in centre.

Material examined – China, Jilin Province, Gongzhuling City, from diseased leaves of *Vaccinium angustifolium*, June 2023, X. H. Li, Y. Y. Zhou and P. Z. Chen (dry cultures JZBH340201– JZBH340202), living cultures JZB340201– JZB340202.

Notes – Two new isolates (JZB340201– JZB340202) are phylogenetically close to *Pes. tumida* and *Pes. appendiculata*. We compared the morphological characters of two species (table 5.4), and found that the holotype of *Pes. tumida* (BJFC-S1891) have wider conidia than *Pes. appendiculata* (6.5–7.5 μm vs. 5–6 μm) and smaller L/W ratio (3.1 vs. 4.2), as well as more and longer basal appendage (1–2 basal appendages, (6.5 –)7–19(–19.5) μm vs. single appendages, 3–5 μm). However, additional strain of *Pes. tumida* (CGMCC 3.23502) described in by Razaghi (2024), have larger ranges of dimension, which have overlapped that of *Pes. appendiculata*. As two species were introduced at the same year (Gu et al., 2022; Peng et al., 2022) without compared with each other, we speculate that the two species have the possibility to be same. According the above information, we currently identify our isolates as *Pes. tumida*, which has been published earlier. Whether *Pes. appendiculata* be synonymized under *Pes. tumida* need to be further studied. *Pestalotiopsis tumida* was introduced from branches and spines of *Rosae chinensis* in China (Peng et al., 2022), which is also the only host reported. This is the first report of *Pes. tumida* on blueberry (*Vaccinium* spp.).

Figure 5.38 Morphological characters of *Pestalotiopsis tumida* (JZB340201)

Figure 5.38 a Colony on PDA after four days; b Colony on PDA after three weeks; c Conidiomata on PDA; d–e Conidiogenous cells; f–g Conidia. Scale bars: d–j=10 μm .

5.3.5 Characterization and Pathogenicity of Three New Host Records Associated with Blueberry Stem Blight

Among the 61 new host records generated from this study, some of them have been reported to cause important diseases on other hosts, while some others have not been reported on diseased plants. In spite of this, their pathogenicity needs to be verified on blueberry for the different susceptibility to pathogen of different hosts. In this study, three species *Colletotrichum temperatum*, *Curvularia austriaca*, and *Diaporthe unshiuensis* associated with blueberry stem blight were selected, their molecular and morphological characters were characterized, and pathogenicity test was conducted.

5.3.5.1 Taxonomy

Colletotrichum temperatum V.P. Doyle, P.V. Oudem. & S.A. Rehner, PLoS ONE 8(12): e51392, 17 (2013) Figure 5.39

Index Fungorum no: IF 801463; Facesoffungi Number: FoF 16980

Classification: Glomerellaceae, Glomerellales, Hypocreomycetidae, Sordariomycetes, Ascomycota, Fungi (Hyde et al., 2024)

Pathogenic on *Vaccinium corymbosum*. **Sexual morph** developed on PNA: *Ascomata* 156–387 × 147–347 μm (\bar{x} = 259.7 × 222.6 μm, n = 15), solitary to clustered, subglobose to obpyriform, dark brown to black. *Asci* 38–64 × 8.5–13 μm (\bar{x} = 49.2 × 10.7 μm, n = 30), 8-spored, obclavate, hyaline. *Ascospores* 15–25.5 × 4–5.5 μm (\bar{x} = 19.0 × 4.90 μm, n=30), uniseriate to biseriate, reniform to lunate, aseptate, hyaline, with granular contents. **Asexual morph** developed on the blueberry stem. *Conidiomata* 295–478 × 213–371 μm (\bar{x} = 390.6 × 290.1 μm, n = 15), acervular, semi-immersed, secreting orange conidial masses. Setae not observed. *Conidiophores* branched, hyaline, septate, smooth-walled. *Conidiogenous cells* 8–18 × 3–5 μm (\bar{x} = 13.5 × 3.8 μm, n = 30), cylindrical to ampulliform, tapering toward the apex, hyaline. *Conidia* 13.5–17 × 5–6 μm (\bar{x} = 15.4 × 5.4 μm, n = 30), subcylindrical, straight, hyaline, aseptate, rounded ends, while some conidia one end rounded and the other slightly acute. *Appressoria* 8–16.5 × 5.5–12.5 μm (\bar{x} = 11.5 × 8.1 μm, n = 30), single, terminal, irregular, olivaceous.

Colony Characters — Colonies on PDA reach 85 mm diam. after six days, white to pale grey, flat with floccose aerial mycelium, reverse greyish white.

Material Examined — CHINA, Jilin Province, Ji'an City, on the diseased stem of *V. corymbosum*, 9 Sep. 2023, X.H. Li (dry cultures JZBH330443, JZBH330444), living cultures JZB330443, JZB330444.

Notes — In the phylogenetic tree of the *Colletotrichum gloeosporioides* species complex, isolates generated in this study (JZB330443, JZB330444) clustered with the ex-type of *Colletotrichum temperatum* (CBS 133122) with 85% ML bootstrap support and 1.00 BYPP (Figure 5.40). Morphologically, ascospore length of JZB330444 (15–25.5 μm , \bar{x} = 19.0 μm) cultured on PNA is larger than that of the ex-type (CBS 133122, 14.3–15.3 μm) of *C. temperatum* cultured on CMA, and the conidium width of JZB330444 (5–6 μm , \bar{x} = 5.4 μm) cultured on PNA is larger than that of the ex-type (CBS 133122, 4.5–4.7 μm) of *C. temperatum* cultured on CMA (Liu et al., 2022), the differences may be caused by the difference of the medium. *Colletotrichum temperatum* was introduced by Doyle and colleagues (Liu et al., 2022) from the decayed fruit of cranberry (*Vaccinium macrocarpon*) in the USA. This species has also been reported to be associated with grape fruit rot in the USA and cherry leaf spot in China (Bhunjun et al., 2024; Dean et al., 2012). This is the first report of *Colletotrichum temperatum* as a pathogen on *Vaccinium corymbosum*.

Figure 5.40 Phylogenetic tree generated by maximum likelihood (ML) analysis of the combined ITS, *gapdh*, *chs*, *act* and *tub* sequence data of species belonging to *Colletotrichum gloeosporioides* species complex

Figure 5.40 The tree is rooted with *Colletotrichum boninense* (CBS 123755 and CBS 128508). The tree topology of the ML analysis was similar to the Bayesian analysis. The best-scoring RAxML tree with a final likelihood value of -9965.268605 is presented (Figure 2). The matrix had 818 distinct alignment patterns, with 9.03% of undetermined characters or gaps. Estimated base frequencies were as follows: A = 0.226449, C = 0.302220, G = 0.238651, T = 0.232680; substitution rates AC = 1.012333, AG = 2.893451, AT = 1.007060, CG = 0.896810, CT = 4.881719, GT = 1.000000; gamma distribution shape parameter α = 1.066665. RAxML bootstrap support values

$\geq 50\%$ and Bayesian posterior probabilities ≥ 0.90 (BYPP) are shown near the nodes. The scale bar indicates 0.02 changes. The ex-type strains are in bold and isolates from the current study are in red.

Curvularia austriaca Y. Marín & Crous, in Marín-Felix, Hernández-Restrepo & Crous, Mycol. Progr. 19(6): 564 (2020) Figure 5.41

Index Fungorum no: IF 830045; Facesoffungi Number: FoF 16981

Classification: Pleosporaceae, Pleosporales, Pleosporomycetidae, Dothideomycetes, Ascomycota, Fungi (Hyde et al., 2024).

Pathogenic on *Vaccinium corymbosum*. **Sexual morph:** Not observed. **Asexual morph:** On PDA: *hyphae* 2–4 μm wide, branched, subhyaline to pale brown, septate. *Conidiophores* simple, rarely branched, straight to flexuous, often geniculate at the apex, pale brown, septate. *Conidiogenous cells* 6–14 \times 3–5.5 μm (\bar{x} = 10.0 \times 4.0 μm , n = 10), terminal or intercalary, subcylindrical to slightly swollen, subhyaline to pale brown, smooth-walled. *Conidia* 21–29.5 \times 7.5–12 μm (\bar{x} = 25.5 \times 9.7 μm , n = 30), straight or slightly curved, ellipsoidal to obovoid, middle cells slightly enlarged, smooth-walled to finely verruculose, apical and basal cells hyaline to pale brown, middle cells dark brown in matured conidia, 3 distoseptate, middle septa dark brown. *Hila* 1.5–2.5 μm wide, protruding, darkened, thickened. *Chlamydospores* not observed.

Culture characteristics — Colonies on PDA reach 85 mm diam. after 7 days, margin lobulate, luteous to orange, umber in the centre, aerial mycelium moderate, slightly cottony; reverse luteous to orange.

Material Examined — CHINA, Jilin Province, Ji'an City, on the diseased stem of *V. corymbosum*, 9 Sep. 2023, X.H. Li (dry cultures JZBH3720001, JZBH3720002), living cultures JZB3720001, JZB3720002.

Notes — Two isolates obtained from the blueberry stems in the present study (JZB3720001 and JZBH3720002) phylogenetically clustered with *Curvularia* strains (CBS 102694, UTHSC 08-2957 and UTHSC 09-3510), with 97% ML bootstrap support and 1.00 BYPP (Figure 5.42). The morphological characters of our isolates are in accordance with the description of *C. austriaca* type (Fu et al., 2019). This species was introduced by Marín-Felix and colleagues from a human (Fu et al., 2019), and no other records from plant hosts afterwards. This is the first report of *C. austriaca* associated with stem blight on *Vaccinium corymbosum*.

Figure 5.42 Phylogenetic tree generated by maximum likelihood analysis of the combined ITS, *gapdh* and *tef* sequence data of species belonging to *Curvularia*

Figure 5.42 The tree is rooted with *Bipolaris maydis* (CBS 136.29), *Johnalcornia aberrans* (CBS 510.91) and *Pyrenophora poae* (BRIP 10953). The ex-type strains are in bold and isolates from the current study are in red. The matrix had

655 distinct alignment patterns, with 17.23% of undetermined characters or gaps. Estimated base frequencies were as follows: A = 0.228223, C = 0.307112, G = 0.244933, T = 0.219732; substitution rates AC = 1.125622, AG = 4.404677, AT = 1.020378, CG = 1.429845, CT = 8.302359, GT = 1.000000; gamma distribution shape parameter $\alpha = 0.636951$. RAxML bootstrap support values $\geq 50\%$ and Bayesian posterior probabilities ≥ 0.90 (BYPP) are shown near the nodes. The scale bar indicates 0.02 changes.

Diaporthe unshiuensis F. Huang, K.D. Hyde & Hong Y. Li, in Huang, Udayanga, Mei, Fu, Hyde & Li, Fungal Biology 119(5): 344 (2015). Figure 5.43

Index Fungorum no: IF 810845; Facesoffungi Number: FoF 09422

Classification: Diaporthaceae, Diaporthales, Diaporthomycetidae, Sordariomycetes, Ascomycota, Fungi

Pathogenic on *Vaccinium corymbosum*. **Sexual morph:** Not observed. *Asexual morph:* On PNA: *Pycnidia* 103–371 \times 80–285 μm ($\bar{x} = 156.9 \times 125.4 \mu\text{m}$, $n = 25$), globose to subglobose, dark brown to black. *Conidiophores* were not observed. *Conidiogenous cells* were not observed. *Alpha conidia* 6–8.5 \times 2–3 μm ($\bar{x} = 6.7 \times 2.7 \mu\text{m}$, $n = 50$), straight to slightly curved, ellipsoidal to fusiform, sometimes with one end obtuse and the other acute, hyaline, smooth, aseptate, biguttulate. *Beta conidia* not observed.

Culture characteristics — Colonies on PDA reach 85 mm diam. after 4 days, white and turning to grey with ageing, reverse white or pale brown pigmentation at the centre.

Material Examined — CHINA, Jilin Province, Ji'an City, on the diseased stem of *V. corymbosum*, 9 Sep. 2023, X.H. Li (dry cultures JZBH320309, JZBH320310), living cultures JZB320309, JZB320310.

Notes — In the phylogenetic analysis, two isolates (JZB320309, JZB320310) obtained from this study formed a well-supported clade with the ex-type strain of *Diaporthe unshiuensis* (ZJUD52), with 100% ML bootstrap support and 1.00 BYPP (Figure 5.44). Morphologically, the two isolates are similar to the ex-type of *D. unshiuensis* (Gomes et al., 2013). *Diaporthe unshiuensis* was first reported by Huang and colleagues (Gomes et al., 2013) as an endophyte on the fruits of *Citrus unshiu* and on asymptomatic branches and twigs of *F. margarita* in China. Subsequently, the

species was also isolated from asymptomatic twigs of *Carya illinoensis* (Norphanphoun et al., 2022) and the healthy root of *M. officinalis* (Hongsanan et al., 2023). However, later it was found as a pathogen causing shoot blight, canker and dieback on fruit trees, including citrus, pear, kiwifruit, grapevine and peach (Dissanayake et al., 2024; Huang et al., 2025; Yang et al., 2018; Manawasinghe et al., 2019; Luo et al., 2022). The species was mostly distributed in China, and also reported from soybean in the USA (Guo et al., 2020). This is the first report of *D. unshiuensis* causing stem blight on *Vaccinium corymbosum*.

Figure 5.43 Morphological characters of *Diaporthe unshiuensis* (JZB320309)

Figure 5.43 a An upper view of colonies on the PDA; b Reverse view of colonies on the PDA; c Conidiomata sporulating on PNA; d Cross section of conidiomata; e Alpha conidia. Scale bars: d = 100 μm ; e = 10 μm .

Figure 5.44 Phylogenetic tree generated by maximum likelihood analysis of combined ITS, *tef*, *tub*, *cal* and *his* sequence data of species belonging to *Diaporthe sojae* species complex

Figure 5.44 The tree is rooted with *D. amygdali* (CBS 126679 and CBS 115620). The tree topology of the ML analysis was similar to the Bayesian analysis. The best-scoring RAxML tree with a final likelihood value of -27986.001494 is presented (Figure 6). The matrix had 1208 distinct alignment patterns, with 19.34% of undetermined characters or gaps. Estimated base frequencies were as follows: A =

0.214688, C = 0.319197, G = 0.242643, T = 0.223473; substitution rates AC = 1.222391, AG = 3.869013, AT = 1.482265, CG = 1.021922, CT = 5.320754, GT = 1.000000; gamma distribution shape parameter $\alpha = 1.100460$. RAxML bootstrap support values $\geq 50\%$ and Bayesian posterior probabilities ≥ 0.90 (BYPP) are shown near the nodes. The scale bar indicates 0.04 changes. The ex-type strains are in bold and isolates from the current study are in red.

5.3.5.2 Pathogenetic assay

The virulence of *Colletotrichum temperatum* (JZB330444), *Curvularia austriaca* (JZB3720002), and *Diaporthe unshiuensis* (JZB320309) was assessed using a detached green shoots assay on *Vaccinium corymbosum* (Fig.5.45). Two weeks post-inoculation, necrotic lesions with dark brown margins were observed on all three treatments. The shoots inoculated with *D. unshiuensis* showed significant lesion development. Reddish-brown lesions extended upwards and downwards from the inoculation point, with the emergence of the brownish conidiomata that became black upon maturation, either solitary or clustered in groups of 3–5 conidiomata. On the shoots inoculated with *Colletotrichum* and *Curvularia*, lesions developed slowly, while dense black mycelia of *Curvularia* and fruiting bodies of *Colletotrichum* appeared at the inoculation point, leading to blight and necrosis of plant tissue. Interestingly, black ascomata and conidiomata secreting conidial masses of *Colletotrichum* appeared simultaneously. Twenty-one days after inoculation, *D. unshiuensis* developed the largest lesions (3.08 cm), while *C. temperatum* and *Curvularia austriaca* were less aggressive, with lesions of 0.75 and 0.65 cm, respectively. No lesions developed on the shoots inoculated with PDA discs. Koch's postulates were fulfilled by re-isolating original fungi from symptomatic stems.

Figure 5.45 Pathogenicity assay on *Vaccinium corymbosum* shoots (cv. 'Duke')

Figure 5.45 a Control treatment, b Inoculated by *Diaporthe unshiuensis*, c Inoculated by *Curvularia austriaca*, d Inoculated by *Colletotrichum temperatum*, e–h Conidiomata of *Diaporthe unshiuensis* on the shoot lesions, i Mycelia of *Curvularia austriaca* on the shoot lesion, j Ascomata and conidiomata produced by *Colletotrichum temperatum* on the shoot lesion, k Ascomata of *Colletotrichum temperatum* on the shoot lesion, l Conidiomata of *Colletotrichum temperatum* on the shoot lesion.

5.3.6 Summary

In this section, micro-fungi associated with leaf, stem and root diseases from five provinces in China were identified and analysed. 429 isolates were identified to 90 species of 40 genera, the isolation source and collecting region of each species were listed. The isolation ratio of the genera among all the isolates was presented, and their distributions in different plant parts and collecting regions were further analysed. The dominant fungal group pestalotioid fungi, which accounted for more than 25% of the total isolates, were described, and species with ambiguous phylogeny or morphology were discussed. In addition, three new host record species of *Colletotrichum*, *Curvularia* and *Diaporthe* were described, and their virulence on blueberry stem was verified.

5.4 Discussion

The occurrence of blueberry diseases has been more frequent in recent years. Knowledge of the pathogens is crucial for understanding the occurrence, diagnosis and management of diseases. The current study provided insight into the communities of micro-fungi associated with fruit, leaf, stem and root diseases. The results showed that one disease type is associated with various fungi, suggesting the complexity of the pathogen groups.

5.4.1 Fungal Pathogens of Blueberry Fruit Rots

The perishable nature of blueberry fruits places a constant strain on industrial development. In the current study, among the seven species identified, *Botrytis cinerea* and *Colletotrichum fioriniae* have previously been recognized as important pathogens of blueberry fruit rot (Neugebauer et al., 2024). Grey mould caused by *Botrytis cinerea* could occur in open fields and greenhouses, affecting blueberries from the seedling stage to post-harvest. Rainfall and high humidity during the flowering period of blueberry were more conducive to the occurrence of severe grey mould (Zhai et al., 2024). In China, Dai et al. (2011) isolated *B. cinerea* from blueberry fruits and identified it by morphology. The current study confirmed the species by morphology and phylogeny. For *Colletotrichum fioriniae*, the pathogenicity on blueberry fruit was initially confirmed by MacKenzie et al. (2009) in Florida, USA, while the test strains were regarded as *C. acutatum*. Subsequently, Damm et al. (2012) accommodated those strains into *C. fioriniae*. Eaton et al. (2021) identified *Colletotrichum* causing fruit rots in mixed-fruit orchards in Kentucky, USA and found that all isolates from blueberry in the study belonged to *C. fioriniae*. In recent years, blueberry fruit disease caused by *C. fioriniae* has also been reported in Chile, Mexico, New Zealand and Poland (Pszczółkowska et al., 2016; Castro et al., 2023; Hosking et al., 2024; Covarrubias-Rivera et al., 2025), and the species is first reported in China in the current study. *Botryosphaeria dothidea* is usually reported as the causal agent of blueberry stem blight together with other Botryosphaeriaceae species (Xu et al., 2015). Zhang et al. (2016) investigated fruit rot in Guizhou Province in China, and the symptoms include rot and necrosis of the pedicel, with raised black spots on the fruit surface. The pathogen was

identified as *B. dothidea* by morphology. In this study, *B. dothidea* from fruit rot in Fujian Province was determined by morphology and phylogenetic analysis. *Diaporthe* is well-known as a genus comprising plant pathogens, endophytes or saprobes with a wide distribution and a range of hosts (Gomes et al., 2013; Norphanphoun et al., 2022; Hongsanan et al., 2023). On blueberry, the genus has been reported to cause stem blight and fruit rot or occur as endophytes or latent pathogens (Hilário et al., 2020). *Diaporthe vaccinii* can infect blueberry fruits throughout the entire growth period but often remains latent until the mature stages to harvest (Milholland & Daykin, 1983). Furthermore, *D. nobilis* was reported to cause postharvest rot of blueberry. Nevertheless, the two species were all synonymized under *D. eres* (Hilário et al., 2021). The isolates generated in this study clustered with *D. velutina*, which has been synonymized under *D. anacardii* (Dissanayake et al., 2024). Among the species reduced to synonymy with *D. anacardii*, *D. phillipsii* was introduced from blueberry, associated with stem dieback. According to the two studies, current *D. anacardii* could be a prevalent pathogen in blueberries. *Neopestalotiopsis* is one of the major causal agents of twig dieback, stem blight and canker, as well as leaf spot on blueberry (Santos et al., 2022), while there are rare records of *Neopestalotiopsis* on blueberry fruit diseases. However, *Neopestalotiopsis* spp. have been reported to cause fruit rots on various hosts such as strawberry, plum and avocado (Darapanit et al., 2021). *Fusarium* is a common pathogen on blueberry causing wilt and root rot (Liu et al., 2014; Li et al., 2023), and *F. acuminatum* was reported to cause postharvest fruit rot (Wang et al., 2016). *Cladosporium* is a cosmopolitan genus comprising phytopathogens, saprobes, endophytes and human pathogens (Bensch et al., 2012; Song et al., 2023). As fruit pathogens, *Cladosporium* spp. were reported on dekopon, grapevine, and raspberry (Briceño & Latorre 2008; Xiao et al., 2022; Delisle-Houde et al., 2024), and *Cladosporium cladosporioides* has been reported to cause blueberry fruit rot (Covarrubias-Rivera et al., 2024). Our species from the above three genera, *Cladosporium guizhouense*, *Fusarium annulatum* and *Neopestalotiopsis surinamensis*, are new host records on blueberry. Their pathogenicity on blueberry was confirmed by the appearance of obvious and commonly reported symptoms. Given the important role of the three genera among plant pathogens, these species could be prevalent or latent pathogens on blueberries.

Though many research have highlighted post-harvest management, many post-harvest diseases originate from infections in the field (Saito et al., 2016). Infections start at bloom but can remain latent until fruit ripening, or express symptoms during the postharvest period (Neugebauer et al., 2024). Latent pathogens can be activated by favourable conditions, environmental stresses and mechanical injuries (Neugebauer et al., 2024). Diseased fruits may be harvested together with healthy fruits in a cluster of blueberries, and cause persistent infection by contaminating healthy fruit, resulting in significant losses (Alvarez Osorio et al., 2022; Neugebauer et al., 2024). Thus, preharvest management, such as disease monitoring, agricultural and chemical control, is crucial for protecting fruit health (Saito et al., 2016; Neugebauer et al., 2024).

5.4.2 Fungi Associated with Blueberry Leaf, Stem and Root Diseases

Leaf, stem and root diseases of blueberry showed complexity and mixed infection of pathogens. This study took an overall look on the fungi associated with these diseases. Taken together, the data from the five provinces of this study, *Neopestalotiopsis*, *Pestalotiopsis*, *Alternaria*, *Fusarium*, *Botryosphaeria* and *Diaporthe* are the main fungal genera related to the diseases, which are consistent with previous studies (Barbu et al., 2018; Živković et al., 2021). The distributions of fungal genera in different plant parts and collecting regions were analysed, and the results showed that *Pestalotiopsis*, *Neopestalotiopsis* and *Fusarium* were the dominant genera associated with leaf, stem and root diseases, respectively. Stem samples comprised most genera, and nine genera existed in the three parts. Among the five provinces, Fujian showed the highest fungal diversity. *Neopestalotiopsis*, *Pestalotiopsis*, *Diaporthe*, and *Neofusicoccum* species were mostly distributed in Fujian Province, and isolates of nine genera were isolated only from Fujian Province.

Among all fungi identified, pestalotioid fungi are the predominant groups. However, the classification situation of *Pestalotiopsis* and *Neopestalotiopsis* was rather complicated. The differences in morphological characteristics and the nucleic acid between species are very small, which makes the delimitation of species boundaries very difficult (Razaghi et al., 2024). Though the recently established classification system of Sporocadaceae has promoted a better understanding of this group and facilitated species identification, many species are still difficult to identify when clustered into ambiguous clades. Pestalotioid fungi from this study were described,

and some species with indistinct morphological and molecular differences were suggested to be synonymized.

As an important disease, blueberry stem blight has received special attention in recent years. Botryosphaeriaceae and *Pestalotiopsis*-like species have been recognized as major pathogens (Espinoza et al., 2009; Du et al., 2021), while reports of *Diaporthe* species as pathogens on blueberry have also emerged. To date, 23 *Diaporthe* species have been reported on blueberry, including *Diaporthe ambigua*, *D. amygdali*, *D. asheicola*, *D. australafricana*, *D. baccae*, *D. crousii*, *D. eres*, *D. foeniculina*, *D. hybrida*, *D. leucospermi*, *D. malorum*, *D. nobilis*, *D. oxe*, *D. passiflorae*, *D. phillipsii*, *D. phoenicicola*, *D. rossmaniae*, *D. rudis*, *D. sojiae*, *D. sterillis*, *D. vaccinii*, *D. vacuae*, and *D. viticola* (Doyle et al., 2013; Elfar et al., 2013; Lombard et al., 2014; Sessa et al., 2018; Petrović et al., 2021; Wang et al., 2021; Zhao et al., 2019; Xiao et al., 2023). In this study, *Diaporthe unshiuensis* was reported on blueberry for the first time, while it has been reported to cause grapevine dieback and pear canker (Manawasinghe et al., 2019; Guo et al., 2020), so the species was selected for the pathogenicity test. *Colletotrichum* is also a ubiquitous pathogen. Diseases caused by *Colletotrichum*, usually known as anthracnose, lead to extensive yield and economic loss in agricultural production (Yu et al., 2018). On blueberry, *C. siamense*, *C. kahawae*, *C. karstii*, *C. nymphaeae* and *C. sichuaninense* have been reported to cause anthracnose symptoms on blueberry stems (Hilário et al., 2020). *Colletotrichum temperatum*, associated with grape fruit rot in the USA and cherry leaf spot in China (Bhunjun et al., 2024; Dean et al., 2012), was first recorded on blueberry. *Curvularia* is a filamentous fungus that contains many important plant pathogens causing leaf spots, blight, root rot, and other diseases on cereal crops (Tsushima & Shirasu., 2022; Li et al., 2023). The genus also comprises opportunistic pathogens of humans. *Curvularia austriaca*, identified in this study, was originally reported from humans by Marin-Felix and colleagues (Fu et al., 2019), and is now reported on blueberry for the first time in this study. In summary, *Diaporthe unshiuensis*, *Colletotrichum temperatum*, and *Curvularia austriaca* were selected as representative species for common stem pathogen, pathogen on other parts and new plant pathogen respectively. In the pathogenicity test, *Diaporthe unshiuensis* was confirmed to be pathogenic in blueberry, suggesting that it may become an emerging prevalent pathogen on blueberry. The other two species, *Colletotrichum*

temperatum and *Curvularia austriaca*, showed weak virulence on blueberry in the pathogenicity test, indicating that they may not be the major pathogens of stem blight. Nevertheless, their presence cannot be neglected as they may co-infect with *Diaporthe* on blueberry. Interspecies interactions of pathogenic microorganisms may enhance their impact on hosts (Liu et al., 2020). Additionally, the same species may exhibit different virulence on different host varieties (Bell et al., 2021). The pathogenicity of the above species among blueberry cultivars and the interplay between fungal species need to be further studied.

5.4.3 Research Significance and Application

The study provided a series of fungi associated with blueberry disease, with most of them are new host records. All species generated from fruits can cause different fruit rot symptoms, and three representative species from stem also showed pathogenicity. The result showed the potential of the new host record species as pathogen; thus, pathogenicity of all new collections needs to be studied. In addition, prevalence of blueberry fungi was preliminarily studied, some genera distributed widely, and some specially in one region. Their distributions need to be further verified.

The results of the current study contribute to the understanding of blueberry disease and provide a reference for the development of prevention and control strategies, such as the selection of target fungicide and formulation of calendar. Since the disease severity is affected by pathogens, climate factor and blueberry variety, further studies are necessary to explore the occurrence regularity of diseases, pathogen regional distribution, as well as virulence differences among host cultivars.

CHAPTER 6

CONCLUSIONS

6.1 Overall Conclusion

As important fruit crops in China and globally, cherry, grapevine, and blueberry serve as representative crops for understanding disease occurrence in fruit trees. In this study, cherry leaf spot, grapevine trunk disease, and blueberry diseases were investigated in major cultivation areas in China. Field symptoms were recorded and described, and micro-fungi associated with these diseases were comprehensively identified using morphological characters, phylogenetic analyses and pathogenicity tests. The isolation of known pathogens verified the re-emergence or prevalence of certain species, while the numerous new host records or newly described species may represent emerging pathogens that cause new disease types or aggravate the disease severity. Some of these fungi may also function as saprophytes or antagonists. The diversity of fungi associated with these diseases was revealed, and the relationship between fungi and symptoms, fungal communities and disease types, as well as fungal species distributions, was revealed. In addition, an updated list of pathogens was compiled by integrating the results from previous research with those of the current study.

6.1.1 Fungal Species Associated with Cherry Leaf Spot Disease

Though sweet cherry has a long cultivation history, research on cherry diseases was very limited in the early stages. In the current study, new collections of *Colletotrichum* species were identified, confirming the top three *Colletotrichum* species (*C. gloeosporioides*, *C. fructicola* and *C. aenigma*) causing leaf anthracnose. *Fusarium* species were found to be highly pathogenic to cherry leaves, and all species have been reported to cause diseases on other hosts, suggesting that they could be emerging pathogens for cherry. Furthermore, different symptoms caused by various pathogens were further confirmed. Infected leaves typically exhibit local, spotty necrosis, but the symptoms differ depending on the pathogen. For example, “brown spot” is caused by

Pruniphilomyces circumscissus, “black spot” by *Alternaria alternata*, and “anthracnose” by *Colletotrichum fructicola*. The current study also generated *Colletotrichum*, *Fusarium*, and *Cladosporium* isolates from distinctly different symptom types. While mixed infections of multiple pathogens are common in the field, understanding the differentiated symptoms could help in the preliminary identification of the main pathogen, thus accelerating the disease diagnosis and control. Additionally, *Pestalotiopsis rosae* was first recorded on cherry, as well as the new species *Diaporthe beijingensis*. Finally, all recorded fungal species associated with cherry leaf spot were summarized, along with their isolation regions and identification methods. Although there have been few new pathogen records in other countries in recent years, the pathogens associated with cherry leaf spot in China have shown increasing diversity. Since most pathogens have been reported in Beijing and a few other provinces like Shandong, Sichuan, Liaoning, and Gansu, the distribution of pathogens has not yet shown apparent regularity. Therefore, disease investigations and sample collections need to be conducted across more regions to gain a better understanding of pathogen distribution.

6.1.2 Fungal Species Associated with Grapevine Trunk Disease

Grapevine trunk diseases are constant concerns in nearly all grapevine cultivation areas worldwide. Currently, grapevine trunk diseases are divided into several types according to disease symptoms and pathogens, including Esca complex, Eutypa dieback, Botryosphaeria dieback, black foot and Phomopsis (*Diaporthe*) dieback (Azevedo-Nogueira et al., 2022). In this study, typical GTD samples were collected from eight main cultivation areas in China. A total of forty species were identified, belonging to twenty-one genera. The identification results could be interpreted from three aspects: Firstly, the GTD-associated fungi: Among the fungal genera generated, nine were recognized as GTD pathogens, associated with Botryosphaeria dieback (*Botryosphaeria*, *Lasiodiplodia*, *Diplodia*, *Neofusicoccum*), black foot disease (*Dactylonectria*, *Ilyonectria*, *Cylindrocladiella*), Phomopsis dieback (*Diaporthe*) and Esca complex (*Phaeoacremonium*). Twelve species (*Botryosphaeria dothidea*, *Lasiodiplodia citricola*, *Lasiodiplodia pseudotheobromae*, *Lasiodiplodia theobromae*, *Diplodia seriata*, *Neofusicoccum parvum*, *Dactylonectria novozelandica*, *Dactylonectria alcacerensis*, *Dactylonectria torresensis*, *Dactylonectria macrodidyma*,

Diaporthe eres, *Diaporthe unshiuensis*), which have been reported as important GTD pathogens in both China and globally, were identified, and three species (*Ilyonectria liriodendra*, *Cylindrocladiella viticola*, *Phaeoacremonium iranianum*) reported as GTD pathogens in other countries were recorded in China for the first time. The results verified the prevalent types of grapevine trunk diseases in China and encompassed most of the fungal genera that have been previously reported. However, the identified species showed differences compared to previous studies on GTD pathogens in China. For fungi associated with Botryosphaeria dieback, Botryosphaeriaceae species were highly overlapping with the study of Yan et al. (2013), except for *Neofusicoccum mangiferae*, which was not found at that time. The distribution of these species was in accord with that study. For fungi associated with black foot disease, all *Dactylonectria* species reported by Ye et al. (2021c) were discovered in this study, in addition to the *Ilyonectria liriodendra* and *Cylindrocladiella viticola* that were first identified in China. However, *Cylindrocladiella lageniformis* and *Neonectria* sp. 1 were not found in this study. Regarding fungi associated with Phomopsis dieback, among the ten species previously reported in China (Dissanayake et al., 2015a; Manawasinghe et al., 2019), only two species were identified in this study. For ESCA-associated fungi, only *Phaeoacremonium iranianum* was reported in this study, in contrast to *Fomitiporia punicata* and *Phaeoacremonium minimum*, which were previously reported by Ye et al. (2021b). The results showed the diversity and complexity of GTD pathogens.

Secondly, fungi associated with other diseases: Some species isolated from GTD samples are also common pathogens causing diseases in other parts of the grapevine, such as *Coniella vitis* causing white rot of fruits (Chethana et al., 2017), and *Colletotrichum nymphaeae* and *C. viniferum* causing fruit and twig anthracnose (Yan et al., 2015; Liu et al., 2016). Some species are new host records, while the genera to which they belong are common plant pathogens. For example, *Fusarium* is a common pathogen associated with grapevine decline (Úrbez-Torres et al., 2023). Li et al. (2023) found that *Fusarium* spp. caused similar symptoms to *Dactylonectria macrodidyma*, the pathogen of black foot disease, and can exacerbate the disease severity when co-inoculated with *Dactylonectria macrodidyma*. This phenomenon suggests that *Fusarium* spp. are related to grapevine trunk diseases. For the above fungi isolated from this study, further research is needed to determine whether they are associated with the

occurrence and severity of grapevine trunk disease. Finally, some species, such as *Phaeobotryon rhois* and *Bartalinia kevinhydei*, were reported for the first time on grapevine in this study. These fungi were previously known to cause dieback and leaf spot diseases on other hosts, respectively (Fan et al., 2015; Tibpromma et al., 2020). However, whether they act as pathogens on grapevine needs to be further studied. It is worth noting that although only eight isolates of *Bartalinia kevinhydei* were identified, they were found to be distributed across four provinces. Based on the above results, a diverse range of fungi were associated with grapevine trunk disease, including not only common pathogens but also many other fungi that could potentially be pathogens or saprobes. The impacts of these fungi on grapevine trunk disease remain unclear, and required further studies through pathogenicity tests and antagonistic studies. Additionally, broader and continued collections are needed to verify and expand the fungal list associated with the diseases.

6.1.3 Fungal Species Associated with Blueberry Disease

Currently, blueberry diseases are mainly divided into fruit rot, leaf spot, stem blight and root rot, with fruit rot and stem blight (canker, dieback). In China, though new pathogens continue emerging, most research consists of brief reports on a single new pathogen, and only a few studies have conducted comprehensive identification of groups of pathogens, such as Botryosphaeriaceae species associated with stem blight and *Colletotrichum* species associated with leaf and stem anthracnose. The current study provides an overall insight to the blueberry diseases in China for the first time, with emphasis on fruit rot, leaf spot, stem blight and root rot diseases, which summarized and updated the fungal pathogens. For fruit diseases, pre-harvest diseases were considered in this study, as they directly influence the production of fruits and can potentially serve as the source of postharvest diseases. Typical fruit pathogens like *Botrytis cinerea* and new host records such as *Neopestalotiopsis surinamensis* all showed strong virulence on blueberry fruits. For other diseases, among forty genera identified, *Alternaria*, *Botryosphaeria*, *Diaporthe*, *Fusarium*, *Neopestalotiopsis* and *Pestalotiopsis*, were the dominant genera, accounting for more than 60% of isolation ratio. From a family perspective, Botryosphaeriaceae (including *Botryosphaeria* and *Neofusicoccum*), Sporocadaceae (including *Neopestalotiopsis* and *Pestalotiopsis*), Diaporthaceae (including *Diaporthe*), and Pleosporaceae (including *Alternaria*)

covered the main pathogen groups associated with leaf spot and stem blight in previous studies. Similarly, Nectriaceae (including *Fusarium*, *Neocosmospora*, *Dactylonectria* and *Ilyonectria*) are more likely to be associated with root rot. Analysis of the fungal isolate information revealed certain patterns in fungal distribution. The isolation source (leaf, stem and root) indicated the fungal distribution across different plant parts, while the isolation region (Fujian and Guizhou representing subtropical areas; Heilongjiang, Jilin, and Liaoning representing temperate areas) reflected geographical distribution. *Botryosphaeria dothidea* was the only species widely distributed in all three plant parts and all five collecting areas. *Alternaria alternata* was present in all three plant parts and four collecting areas, except Fujian. *Diaporthe* species were distributed in all three plant parts and across three collecting areas. Certain fungi exhibited distinct regional characteristics. For example, *Bipolaris* species were only isolated from stem blight samples in Heilongjiang, while *Clonostachys* species were exclusive to the three northern provinces. Additionally, *Dactylonectria* and *Ilyonectria*, known black-foot pathogens in grapevines, were found only in root samples. Although these results provide insights into the occurrence of pathogens, they may be influenced by factors such as the selection of collection site, season and sample variability. The current conclusions need to be further verified by large-scale sampling.

As dominant pathogens of blueberry, Pestalotiopsis-like species, were described in detail, the isolates were carefully compared with closely related reference species based on both morphological and phylogenetic analyses. As a result, some species were suggested to be synonymized, though further evidence is required for confirmation.

In conclusion, this study represents the first intensive identification of micro-fungi associated with different diseases of blueberry. The results indicated the diversity of fungal species on blueberry, verified the previously recorded dominant fungal taxa, and expand the records of known fungi on blueberry. The dominant fungal communities identified in this study provide valuable references for future research on disease etiology and disease management.

6.1.4 The Comparison on Fungal Pathogens Between Cherry, Grapevine and Blueberry

Although cherry, grapevine, and blueberry have different growth cycles and distinct disease concerns, comparing dominant pathogens across these hosts enhances

the generalizability and reference value of the results. This study identified both common and host-specific pathogens among the three crops. There are some common pathogens, such as *Colletotrichum* spp. and *Fusarium* spp., in all three crops, though their distribution and species are varied. *Colletotrichum fructicola* was associated with leaf spot in both cherry and blueberry, whereas the *Colletotrichum* species recorded on grapevine trunk disease were not reported in the other two crops. *Fusarium compactum* was isolated from cherry leaves and grapevine trunks, while *F. oxysporum* was isolated in the roots and trunks (stems) of grapevine and blueberry. However, no *Fusarium* species were common to both cherry and blueberry. *Colletotrichum*, *Alternaria* and *Fusarium* were identified as cherry leaf spot pathogens, while *Neopestalotiopsis* and *Pestalotiopsis* species were the main pathogens causing blueberry leaf spot. Some woody pathogens were shared between grapevine and blueberry, including *Botryosphaeria dothidea*, *Neofusicoccum parvum*, and *Diaporthe eres*. Additionally, *Neocosmospora falciformis* and *Neocosmospora solani* were commonly isolated from the roots of both grapevine and blueberry. Pathogens associated with grapevine diseases, such as *Dactylonectria pauciseptata*, *Ilyonectria liriodendri* and *Phaeoacremonium scolyti*, which are linked to black foot and esca complex diseases, were also isolated from blueberry. In conclusion, most fungal pathogens are not strictly host-specific and may cause different disease types on different hosts. However, the dominant pathogens varied significantly across crops. Therefore, studying disease patterns in a crop needs long-term research, and targeted disease management strategies.

6.2 Research Advantages

6.2.1 This study enhanced the understanding of cherry leaf spot disease by identifying new disease types along with their associated pathogens and providing an updated summary of all known CLS pathogens. This represents the first comprehensive generalization of the disease, serving as an important reference for research on disease occurrence patterns and management practices.

6.2.2 This study provided a comprehensive overview of the occurrence of grapevine trunk disease and the diversity of fungi associated with it. Species identified

in the study were compared with previous studies in terms of their distribution and related disease types. Common GTD pathogens were verified, while additional pathogens and newly recorded species were also documented, expanding the current understanding of GTD-associated fungi.

6.2.3 This study represents the first comprehensive study on blueberry diseases and their associated fungal communities. It provides detailed information of fungal taxa identified from fruit rot, leaf spot, stem blight and root rot samples, linking them to the disease types. The study also clarifies fungal distribution patterns and dominant communities. Additionally, a pathogen list recorded in China was compiled, offering valuable insights for future research and disease management.

6.2.4 This study integrates plant disease research and fungal taxonomy, addressing the inconsistencies in pathogen identification. It provides a clarified framework for identifying fungal pathogens and offers a detailed interpretation of the latest classification of important pathogens.

6.3 Future Work

6.3.1 Continuous monitoring of the cherry leaf spot pathogens is essential to prevent disease outbreaks. Additionally, the development of rapid detection technologies is crucial for early and efficient field diagnosis. For other secondary CLS pathogens, such as *Diaporthe* and Didymellaceae species, further investigations are needed to confirm whether they represent emerging pathogens or occur incidentally. *Cladosporium*, a common genus associated with cherry leaf spot, has been linked to specific symptom types; however, its relationship with symptom expression requires further pathogenicity testing. *Pruniphilomyces circumscissus*, an early-recognized pathogen, has yet to be classified using multi-locus phylogenetic analysis. Although recent laboratory studies have identified this species, its pathogenicity remains unverified due to its difficulty in sporulation on artificial media. Future research will focus on clarifying its taxonomy and confirming its role in CLS development.

6.3.2 Grapevine trunk diseases (GTD) are a global concern with no effective control methods despite extensive research. Their underlying mechanisms remain

unclear. This study identified all fungi isolated from GTD samples, recording 12 new host associations and 22 new records on grapevine in China. For species previously reported as GTD pathogens in other countries but newly found in China, pathogenicity tests are needed to confirm their role. Other new host records can be categorized based on prior reports: potential pathogens require pathogenicity tests to assess virulence, while potential biocontrol fungi need antagonistic tests to evaluate their efficacy. Since many GTD pathogens are opportunistic, their infections are influenced by environmental factors and the microbiome. Studying co-infections among selected pathogens could help understand their interactions. Additionally, expanding disease surveys and sample collection across more regions in China will provide valuable reference data.

6.3.3 This study provides the dominant fungal communities identified, along with a summary of important pathogens previously reported on blueberry diseases. However, the findings are based on data from only one year and a limited range of collection sites. To ensure broader applicability, further investigations and additional sample collections are needed. Blueberry orchards should be selected from a wider range of regions, including other major cultivation areas and varying climate zones. When comparing fungal compositions across different regions, it is crucial to collect an adequate and equal number of samples within a similar timeframe. Future analyses will focus on how disease types, fungi, and community distribution change over time, as well as the correlation between symptoms and pathogens. Pathogenicity tests will be conducted on prevalent fungi, and species with high virulence will be inoculated on living plants, both alone and in combination with other pathogens. Additionally, leaf litter, rhizosphere soil, and adjacent plants will be sampled to study the life cycle of related fungi and the potential for host jump or host shift.

Abstract: Sweet cherry is an important fruit crop in China with a high economic value. From 2019 to 2020, a leaf spot disease was reported, with purplish-brown circular lesions in three cultivating regions in China. Twenty-four *Fusarium* isolates were obtained from diseased samples and were identified based on morphological characteristics and multi-locus phylogenetic analyses. Seven species, including *F. luffae* (7 isolates), *F. lateritium* (6 isolates), *F. compactum* (5 isolates), *F. nygamai* (2 isolates), *F. citri* (2 isolates), *F. ipomoeae* (1 isolate) and *F. curvatum* (1 isolate) were identified. The pathogenicity test showed that analyzed strains of all species could produce lesions on detached cherry leaves. Therefore, *Fusarium* was proved to be a pathogen of cherry leaf spots in China. This is the first report of *F. luffae*, *F. compactum*, *F. nygamai*, *F. citri*, *F. ipomoeae* and *F. curvatum* on sweet cherry in China.

Keywords: *Prunus avium*; *Fusarium*; phylogeny; morphology; pathogenicity

1. Introduction

Sweet cherry (*Prunus avium* L.) is an economically important fruit crop widely planted in temperate regions worldwide. The cherry industry in China developed rapidly in the last decade, with 233,000 ha of cultivation area and a yield of 1,700,000 tons in 2019 [1,2]. Even with ideal conditions, various diseases occur on cherries, among which leaf spot is one of the most common and widespread [3]. Since the first report from the USA in 1878, the disease has spread quickly and occurred in most growing areas around the world [4]. The disease causes premature defoliation of leaves, the reduction of tree vigor and winter hardiness, and even tree death, leading to a bad quality of cherries [5]. *Blumeriella jaapii* was regarded as the causal agent of cherry leaf spot disease in Europe and North America [6]. In addition, several other associated fungi were reported. In Israel, the pathogen of cherry leaf spot was identified as *Cercospora circumscissa*, which caused a 40% yield loss in 1975 [7]. Additionally, *Alternaria alternata* and *Pseudocercospora pruni-persicicola* were reported as causing leaf spot in Greece and Korea, respectively [8,9]. In China, *Alternaria cerasi* and *Passalora circumscissa* were identified to cause “black spot” and “brown spot” of sweet cherry according to their morphology in the early days, respectively [10,11]. In recent years, more pathogenic species have been reported based on morphological characterization coupled with phylogenetic analysis, including four *Alternaria* species, three *Colletotrichum* species and four Didymellaceae species [3,12,13]. In this study, *Fusarium* spp. were isolated from cherry leaf spots for the first time, which supplemented the pathogen variety of the disease.

2. Results

2.1. Symptom Observation, Sample Collection and Fungal Isolation

Fifteen leaf spot samples were collected from sweet cherry trees cultured in open fields with the following symptoms, (1) small purple-brownish spots which may merge

Morphological and molecular characterization of *Cladosporium* species on sweet cherry in Beijing, China

Abstract

Cladosporium is a ubiquitous fungal genus with a wide ecological distribution and host range, which plays different roles as pathogen, endophyte and saprobe. The objective of this study was to characterize *Cladosporium* species isolated from sweet cherry (*Prunus avium*) with leaf spot symptoms, using morphological characteristics and phylogenetic analyses based on the internal transcribed spacers (ITS), partial actin (*act*) and translation elongation factor-1 α (*tef1*) gene regions. A total of six species, *C. anthropophilum*, *C. asperulatum*, *C. cladosporioides*, *C. ramotenellum*, *C. rectoides* and *C. tenuissimum*, were identified including five new host records except for *C. cladosporioides*. The present study enhances the knowledge of fungal species associated with sweet cherry.

Keywords: *Prunus avium*, *Cladosporium* species, morphology, phylogeny

INTRODUCTION

Cladosporium is a monophyletic genus in *Cladosporiaceae*. It is one of the largest genera of dematiaceous hyphomycetes with coronate structure, conidia in acropetal chains and *Davidiella* teleomorphs (David 1997; Bensch et al., 2010). Currently, there are 896 records of *Cladosporium* species in the Index Fungorum (<https://www.indexfungorum.org/>; accessed on 25 October 2023). *Cladosporium* species have been isolated from a wide range of substrates including plants, soil, food, clinical and other samples, as well as outdoor and indoor air (Bensch et al., 2012; Sandoval-Denis et al., 2016; Bensch et al., 2018).

Members of *Cladosporium* exist on various plants as saprobes, endophytes and pathogens (Bensch et al., 2012). Leaf spots caused by *Cladosporium* species have been observed in many plants, including vegetables like spinach (du Toit and Derie, 2012), ornamental crops like carnation (Xie et al., 2022), and forage crops like alfalfa (Han et al., 2019). In addition, some of the species showed antagonistic potential on phytopathogens. For example, *C. cladosporioides* could reduce apple scab in leaves and fruits (Köhl et al., 2015), and *C. herbarum* has the biocontrol ability of *Eutypa dieback* of grapevine (Munkvold and Marois, 1993).

Sweet cherry (*Prunus avium*) is a vital fruit crop cultivated widely in temperate regions of Asian, European, and American countries. Various fungi associated with sweet cherries have been reported as pathogens or endophytes (Aghdam and Fotouhifar, 2017; Chethana et al., 2019). However, few reports of *Cladosporium* were on sweet cherry. Only *C. cladosporioides* and *C. phyllophilum* were reported to be isolated from imported buds of sweet cherry (Bensch et al., 2012).

The current study focuses on *Cladosporium* species associated with sweet cherry by morphological observation and multi-locus phylogenetic analyses, revealing the re-occurrence of this taxa.

Zhou YY, Zhang W, Wu LN, Zhang J, Tan HY, Chethana KWT, Manawasinghe IS, Liu M, Li XH, Hyde KD, Yan JY 2023 – Diversity of fungal communities associated with grapevine trunk diseases in China. Mycosphe 14(1), 1340–1435, Doi 10.5943/mycosphe/14/1/15

Abstract

Grapevine trunk diseases (GTDs) are one kind of the most common and destructive diseases worldwide which challenge the sustainable development of the grape industry and cause serious economic loss. From 2020 to 2022, grapevine trunk disease samples were collected from eight provinces in China and associated fungi were identified based on phylogenetic analyses and morphological observations. A total of 199 isolates were obtained, representing 40 species belonging to 21 genera in 10 families. Twenty-one species are reported as the first records in China and 13 as the first records on grapevine worldwide. *Diaporthe*, Botryosphaeriaceae, *Cylindrocarpum*-like and *Fusarium*-like genera were the most frequently isolated taxa. *Bartalinia*, *Botryosphaeria* and *Dactylonectria* species were widely distributed in China. The study provides an insight into the diversity of fungal species on the diseased grapevine, among which some may play the role of common or potential pathogens, endophytes, and saprobes. Relevant results provide the basis for further research on the interactions among fungal communities and strategies for managing grapevine trunk diseases.

Keywords – diversity – grapevine trunk diseases – morphology – new records – phylogenetic analyses

Introduction

Grapevine (*Vitis* spp.) is one of the most widely planted and economically important fruit crops in the world since historic times and served as table fruits or processed into wine and raisin (Gramaje et al. 2018). China ranks third among grape-cultivation countries, with a cultivation area of 783 Kha in 2021 (OIV 2022) with 15 million metric tons of annual production. However, *Vitis* species are susceptible to many fungal diseases. Among these, the grapevine trunk diseases (GTDs) are one of the most destructive diseases in the world, which have drawn considerable attention in the last decades (Reis et al. 2019). They reduce vineyard longevity, productivity and quality, and the loss caused is estimated to be \$1.5 billion per year (Hofstetter et al. 2012, Dissanayake et al. 2015a). The grapevine trunk diseases include a group of diseases associated with diverse vascular

Abstract: Blueberry has been a burgeoning fruit in China in recent years, but its perishable nature places a constant strain on industrial development. To determine the pathogens infecting blueberry fruits, diseased samples were collected from Guizhou and Fujian Provinces. Isolates from the samples were identified by morphological characterization and phylogenetic analyses. Pathogenicity assays were conducted on fresh blueberry fruits using spore suspensions. Sixteen isolates were identified as seven species, namely, *Botryosphaeria dothidea*, *Botrytis cinerea*, *Cladosporium guizhouense*, *Colletotrichum fioriniae*, *Diaporthe anacardii*, *Fusarium annulatum*, and *Neopestalotiopsis surinamensis*, and their pathogenicity on blueberry fruits were confirmed following Koch's postulates. The current study reported *Cladosporium guizhouense*, *Fusarium annulatum*, and *Neopestalotiopsis surinamensis* for the first time on blueberry. The study (1) demonstrated that fruit rot disease results from a mixed infection of multiple pathogens; and (2) expanded the understanding of causal agents of blueberry fruit rot during the growth stage, highlighting their potential as latent pathogens that contribute to post-harvest losses. Relevant results provide a reference for the etiological research and disease management in blueberry fruit diseases.

Keywords: *Vaccinium* spp.; new host records; phylogenetic analysis; pathogenicity

1. Introduction

Blueberry (*Vaccinium* spp.) has been cultivated for more than 100 years, and the industry has developed rapidly in the recent years, with the global production more than doubling in the last decade (U.S. Department of Agriculture 2021). As of 2023, the global cultivation area of blueberry comes up to 262,417 hectares, with a global production of 1.78 million tons, and China is ranked first, producing 0.56 million tons (International Blueberry Organization 2024). Blueberries are recognized as a “superfruit” for their rich nutrients, including vitamins (C and K), minerals (calcium, iron, magnesium, manganese, and zinc), dietary fiber (2.4–3.5% of fruit weight), and polyphenols (anthocyanins and flavonols) [1]. Specifically, anthocyanin flavonoids, which account for up to 60% of the total

Abstract: Stem blight is a significant disease affecting blueberries worldwide, caused by various pathogens. This study investigated stem blight disease in Ji'an, Jilin Province, China. Fungi isolated from diseased stems were identified as *Colletotrichum temperatum*, *Curvularia austriaca*, and *Diaporthe unshiuensis* based on morphological characters and multi-locus phylogenetic analyses using the internal transcribed spacer (ITS) region, glyceraldehyde 3-phosphate dehydrogenase (*gapdh*), chitin synthase (*chs*), actin (*act*), β -tubulin (*tub2*), the translation elongation factor 1-alpha (*tef1-a*), calmodulin (*cal*), and histone 3 (*his3*) regions. Pathogenicity test was conducted on detached green blueberry shoots, all shoots inoculated by mycelium plugs presented necrotic lesions with dark brown margins, while the control (PDA plugs) group did not show any symptoms. Koch's postulates were confirmed by re-isolating the inoculated pathogen from the disease symptoms. The study provides three new host–pathogen records of fungi associated with blueberry stem blight.

1. Introduction

Blueberry (*Vaccinium* spp.), well known for its rich bioactive compounds that promote health, is widely recognized as a “super fruit” [1]. The high nutritional and economic value of blueberries has driven rapid development in the blueberry industry. Over the past five years, the global area under cultivation and blueberry yield increased from 198,817 ha and 1.28 million tons to 262,417 ha and 1.78 million tons, respectively [2]. In China, blueberries are now planted in 26 of 34 provinces [3].

Despite the high resilience of blueberries, various diseases inevitably emerge throughout their lifespan, including fruit rot, stem blight, leaf spot, powdery mildew, and root rot, which pose serious threats to plant health [4]. Among these various diseases, stem blight is both common and severe, resulting in reduced production and economic losses [5]. In New Zealand, the disease incidence has reached 18%, causing \$500,000 in annual losses [6]; in Chile, the incidence rate ranges from 15 to 45% [7]. As the top producer of blueberries, China also suffered 10% to 25% of crop damage from the disease [8].

Stem blight is caused by several fungal pathogens that infect plants through wounds or natural openings, leading to vascular damage, wood discoloration, and even the death of the plant [5,9]. As a general term, stem blight is also known as stem canker or dieback. Typical symptoms of the disease are reddish-brown to gray-brown lesions on stems, shoots, or
